# Decision Properties of Regular Languages 

General Discussion of "Properties"<br>The Pumping Lemma<br>Membership, Emptiness, Etc.

## Properties of Language Classes

- A language class is a set of languages.
- We have one example: the regular languages.
- We'll see many more in this class.

Language classes have two important kinds of properties:

1. Decision properties.
2. Closure properties.

## Representation of Languages

Representations can be formal or informal.

- Example (formal): represent a language by a RE or DFA defining it.
Example: (informal): a logical or prose statement about its strings:
- $\left\{0^{n} 1^{n} \mid n\right.$ is a nonnegative integer\}
- "The set of strings consisting of some number of 0 's followed by the same number of 1 's."

## Decision Properties

- A decision property for a class of languages is an algorithm that takes a formal description of a language (e.g., a DFA) and tells whether or not some property holds.
- Example: Is language L empty?

## Subtle Point: Representation Matters

$\checkmark$ You might imagine that the language is described informally, so if my description is "the empty language" then yes, otherwise no.
But the representation is a DFA (or a RE that you will convert to a DFA).
Can you tell if $L(A)=\varnothing$ for DFA $A$ ?

## Why Decision Properties?

- When we talked about protocols represented as DFA's, we noted that important properties of a good protocol were related to the language of the DFA.
- Example: "Does the protocol terminate?"
= "Is the language finite?"
- Example: "Can the protocol fail?" = "Is the language nonempty?"

## Why Decision Properties - (2)

-We might want a "smallest"
representation for a language, e.g., a
minimum-state DFA or a shortest RE.

- If you can't decide "Are these two
languages the same?"
- I.e., do two DFA's define the same language?
You can't find a "smallest."

## Closure Properties

- A closure property of a language class says that given languages in the class, an operator (e.g., union) produces another language in the same class.
- Example: the regular languages are obviously closed under union, concatenation, and (Kleene) closure.
- Use the RE representation of languages.

## Why Closure Properties?

1. Helps construct representations.
2. Helps show (informally described) languages not to be in the class.

## Example: Use of Closure Property

We can easily prove $L_{1}=\left\{0^{n} 1^{n} \mid n \geq 0\right\}$ is not a regular language.
$\Delta L_{2}=$ the set of strings with an $=$ number of 0's and 1's isn't either, but that fact is trickier to prove.
Regular languages are closed under $\cap$.
If $L_{2}$ were regular, then $L_{2} \cap L\left(\mathbf{O}^{*} \mathbf{1}^{*}\right)=$ $\mathrm{L}_{1}$ would be, but it isn't.

## The Membership Question

- Our first decision property is the question: "is string w in regular language L?"
Assume $L$ is represented by a DFA A.
- Simulate the action of A on the sequence of input symbols forming w.

## Example: Testing Membership

## Example: Testing Membership

## What if the Regular Language Is not Represented by a DFA?

There is a circle of conversions from one form to another:

## The Emptiness Problem

$\checkmark$ Given a regular language, does the language contain any string at all.
$\checkmark$ Assume representation is DFA.
Construct the transition graph.
Compute the set of states reachable from the start state.
$\rightarrow$ If any final state is reachable, then yes, else no.

## The Infiniteness Problem

Is a given regular language infinite?
Start with a DFA for the language.
$\checkmark$ Key idea: if the DFA has $n$ states, and the language contains any string of length $n$ or more, then the language is infinite.

Otherwise, the language is surely finite.

- Limited to strings of length $n$ or less.

## Proof of Key Idea

-If an n-state DFA accepts a string w of length $n$ or more, then there must be a state that appears twice on the path labeled $w$ from the start state to a final state.

Because there are at least $\mathrm{n}+1$ states along the path.

## Proof - (2)

$$
w=x y z
$$

Then $x y^{i} z$ is in the language for all $i \geq 0$.

Since $y$ is not $\epsilon$, we see an infinite number of strings in $L$.

## Infiniteness - Continued

We do not yet have an algorithm.

- There are an infinite number of strings of length > n, and we can't test them all.

Second key idea: if there is a string of length $\geq \mathrm{n}$ (= number of states) in L , then there is a string of length between n and $2 \mathrm{n}-1$.

## Proof of $2^{\text {nd }}$ Key I dea

- We can choose $y$ to be the first cycle on the path.
So $|x y| \leq n$; in particular, $1 \leq|y| \leq n$.
Thus, if $w$ is of length $2 n$ or more, there is a shorter string in $L$ that is still of length at least $n$.
Keep shortening to reach [n, 2n-1].

## Completion of Infiniteness Algorithm

Test for membership all strings of length between n and $2 \mathrm{n}-1$.

- If any are accepted, then infinite, else finite.
$\checkmark$ A terrible algorithm.
Better: find cycles between the start state and a final state.

## Finding Cycles

1. Eliminate states not reachable from the start state.
2. Eliminate states that do not reach a final state.
3. Test if the remaining transition graph has any cycles.

## The Pumping Lemma

- We have, almost accidentally, proved a statement that is quite useful for showing certain languages are not regular.
Called the pumping lemma for regular languages.

## Statement of the Pumping Lemma

Number of
For every regular language $L$
states of
DFA for $L$
There is an integer $n$, such that
For every string $w$ in $L$ of length $\geq n$ We can write $w=x y z$ such that:

1. $|x y| \leq n$.
2. $|y|>0$.
3. For all $i \geq 0, x y^{i} z$ is in $L$.

Labels along first cycle on path labeled w

## Example: Use of Pumping Lemma

$\checkmark$ We have claimed $\left\{0^{k} 1^{k} \mid k \geq 1\right\}$ is not a regular language.
Suppose it were. Then there would be an associated n for the pumping lemma.
Let $w=0^{n} 1^{n}$. We can write $w=x y z$, where $x$ and $y$ consist of 0 's, and $y \neq \epsilon$.
$\checkmark$ But then xyyz would be in L, and this string has more 0's than 1's.

## Decision Property: Equivalence

Given regular languages $L$ and $M$, is $L=M$ ?
$\checkmark$ Algorithm involves constructing the product DFA from DFA's for $L$ and $M$.
Let these DFA's have sets of states Q and R, respectively.
$\checkmark$ Product DFA has set of states $\mathrm{Q} \times \mathrm{R}$.

- I.e., pairs [q, r] with $q$ in $Q, r$ in $R$.

## Product DFA - Continued

Start state $=\left[q_{0}, r_{0}\right]$ (the start states of the DFA's for $L, M$ ).
Transitions: $\delta([q, r], a)=$ $\left[\delta_{L}(q, a), \delta_{M}(r, a)\right]$

- $\delta_{L}, \delta_{M}$ are the transition functions for the DFA's of L, M.
- That is, we simulate the two DFA's in the two state components of the product DFA.

## Example: Product DFA

## Equivalence Algorithm

- Make the final states of the product DFA be those states [ $q, r$ ] such that exactly one of $q$ and $r$ is a final state of its own DFA.

Thus, the product accepts $w$ iff $w$ is in exactly one of $L$ and $M$.

## Example: Equivalence

## Equivalence Algorithm - (2)

$\checkmark$ The product DFA's language is empty iff $L=M$.
But we already have an algorithm to test whether the language of a DFA is empty.

## Decision Property: Containment

Given regular languages $L$ and $M$, is $L \subseteq M$ ?
Algorithm also uses the product automaton.
How do you define the final states [q, r] of the product so its language is empty iff $\mathrm{L} \subseteq \mathrm{M}$ ?

Answer: $q$ is final; $r$ is not.

## Example: Containment

Note: the only final state is unreachable, so containment holds.

# The Minimum-State DFA for a Regular Language 

- In principle, since we can test for equivalence of DFA's we can, given a DFA $A$ find the DFA with the fewest states accepting $L(A)$.
Test all smaller DFA's for equivalence with $A$.
But that's a terrible algorithm.

## Efficient State Minimization

$\checkmark$ Construct a table with all pairs of states.
$\rightarrow$ If you find a string that distinguishes two states (takes exactly one to an accepting state), mark that pair.

- Algorithm is a recursion on the length of the shortest distinguishing string.

## State Minimization - (2)

Basis: Mark a pair if exactly one is a final state.
$\checkmark$ Induction: mark [q, r] if there is some input symbol $a$ such that $[\delta(q, a), \delta(r, a)]$ is marked.

- After no more marks are possible, the unmarked pairs are equivalent and can be merged into one state.

## Transitivity of "I ndistinguishable"

-If state p is indistinguishable from q, and $q$ is indistinguishable from $r$, then $p$ is indistinguishable from $r$.

- Proof: The outcome (accept or don't) of $p$ and $q$ on input $w$ is the same, and the outcome of $q$ and $r$ on $w$ is the same, then likewise the outcome of $p$ and $r$.

## Constructing the MinimumState DFA

$\checkmark$ Suppose $\mathrm{q}_{1}, \ldots, \mathrm{q}_{\mathrm{k}}$ are indistinguishable states.
Replace them by one state q.
Then $\delta\left(q_{1}, a\right), \ldots, \delta\left(q_{k}, a\right)$ are all indistinguishable states.

- Key point: otherwise, we should have marked at least one more pair.
Let $\delta(q, a)=$ the representative state for that group.

## Example: State Minimization

|  | r | b |
| :---: | :---: | :---: |
| $\mathbf{\{ 1 \}}$ | $\{2,4\}$ | $\{5\}$ |
| $\{2,4\}$ | $\{2,4,6,8\}$ | $\{1,3,5,7\}$ |
| $\{5\}$ | $\{2,4,6,8\}$ | $\{1,3,7,9\}$ |
| $\{2,4,6,8\}$ | $\{2,4,6,8\}$ | $\{1,3,5,7,9\}$ |
| $\{1,3,5,7\}$ | $\{2,4,6,8\}$ | $\{1,3,5,7,9\}$ |
| $*$ | $\{1,3,7,9\}$ | $\{2,4,6,8\}$ |
| $*\{1,3,5,7,9\}$ | $\{2,4,6,8\}$ | $\{1,3,5,7,9\}$ |

Here it is with more convenient state names

Remember this DFA? It was constructed for the chessboard NFA by the subset construction.

## Example - Continued

Start with marks for the pairs with one of the final states F or G .

## Example - Continued

|  | $G$ | $F$ | $E$ | $D$ | $C$ | $B$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $A$ | $x$ | $x$ |  |  |  |  |
| $B$ | $x$ | $x$ |  |  |  |  |
| $C$ | $x$ | $x$ |  |  |  |  |
| $D$ | $x$ | $x$ |  |  |  |  |
| $E$ | $x$ | $x$ |  |  |  |  |

I nput r gives no help, because the pair [B, D] is not marked.

## Example - Continued

But input $b$ distinguishes $\{A, B, F\}$ from $\{C, D, E, G\}$. For example, $[A, C]$ gets marked because [C, F] is marked.

## Example - Continued

[C, D] and [C, E] are marked because of transitions on $b$ to marked pair [F, G].

## Example - Continued

[ $\mathrm{A}, \mathrm{B}$ ] is marked
because of transitions on $r$ to marked pair [B, D].

[D, E] can never be marked, because on both inputs they go to the same state.

## Example - Concluded

| r | b |  |  | $r$ | b |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\rightarrow \mathrm{AB}$ | C | $\rightarrow$ |  | A B | C |
| B D | E |  |  | B H | H |
| $C D$ | F |  |  | C | F |
| D D | G |  |  | H | G |
| ED | G |  |  |  |  |
| * FD | C |  |  | H | C |
| * G D | G |  | * | G H | G |

|  | G | F | E | D | C | B |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| A | X | X | $x$ | x | $\times$ | x |
| B | $x$ | X | $x$ | $\times$ | $\times$ |  |
| C | x | X | $x$ | $\times$ |  |  |
| D | x | x |  |  |  |  |
| E |  | x |  |  |  |  |
|  | $x$ |  |  |  |  |  |

Replace D and E by H.
Result is the minimum-state DFA.

## Eliminating Unreachable States

$\checkmark$ Unfortunately, combining indistinguishable states could leave us
with unreachable states in the
"minimum-state" DFA.
-Thus, before or after, remove states that are not reachable from the start state.

## Clincher

We have combined states of the given DFA wherever possible.
-Could there be another, completely unrelated DFA with fewer states?

No. The proof involves minimizing the DFA we derived with the hypothetical better DFA.

## Proof: No Unrelated, Smaller DFA

Let A be our minimized DFA; let B be a smaller equivalent.

- Consider an automaton with the states of A and B combined.
-Use "distinguishable" in its contrapositive form:
- If states $q$ and $p$ are indistinguishable, so are $\delta(q, a)$ and $\delta(p, a)$.

## Inferring Indistinguishability

Start states of $A$ and $B$ b
a

indistinguishable indistinguishable indistinguishable because L(A)
$=\mathrm{L}$ (B).

## Inductive Hypothesis

$\checkmark$ Every state q of A is indistinguishable from some state of $B$.

- Induction is on the length of the shortest string taking you from the start state of A to q.

## Proof - (2)

Basis: Start states of $A$ and $B$ are indistinguishable, because $L(A)=L(B)$.

- Induction: Suppose $w=x a$ is a shortest string getting $A$ to state $q$.
By the IH, $x$ gets A to some state $r$ that is indistinguishable from some state $p$ of $B$.
Then $\delta(r, a)=q$ is indistinguishable from $\delta(p, a)$.

## Proof - (3)

However, two states of A cannot be indistinguishable from the same state of B, or they would be indistinguishable from each other.

- Violates transitivity of "indistinguishable."

Thus, B has at least as many states as A.
