# CS109A Notes for Lecture 3/13/95

#### **Database Relations**

The relational model upon which modern database systems are based uses a slight variant of k-ary relations from set theory.

- Database relations are "tables" with
  - Columns headed by attributes (column names).
  - □ Rows called *tuples* that are members of the relation.

Class	Weight	Guns	Caliber	Туре	Country
Alaska	28000	9	12	BC	USA
$\operatorname{Colorado}$	32000	8	16	BB	USA
$\mathbf{Fuso}$	35000	12	14	BB	Japan
$\operatorname{Hood}$	41000	8	15	BC	Gt. Br.
Iowa	46000	9	16	BB	USA
Ise	36000	12	14	BB	Japan
King George V	38000	10	14	BB	Gt. Br.
Kongo	32000	8	14	BC	Japan
Nagato	38000	8	16	BB	Japan
Nelson	34000	9	16	BB	Gt. Br.
Nevada	29000	10	14	BB	USA
New Mexico	33000	12	14	BB	USA
New York	27000	10	14	BB	USA
North Carolina	37000	9	16	BB	USA
Pennsylvania	33000	12	14	BB	USA
Queen Elizabeth	31000	8	15	BB	Gt. Br.
Renown	32000	6	15	BC	Gt. Br.
Revenge	29000	8	15	BB	Gt. Br.
South Dakota	37000	9	16	BB	USA
Tennessee	32000	12	14	BB	USA
Wyoming	26000	12	12	BB	USA
Yamato	65000	9	18	BB	Japan

Fig. 1. The relation *Classes* of capital ships of the major WW-II naval powers.

**Example:** In Fig. 1 is a table of capital ship classes.

- The six columns correspond to attributes class name, tonnage, number of guns, caliber of guns, type, and country.
- For example, the first row says that ships of the Alaska class displaced 28,000 tons, mounted nine 12-inch guns, was a class of battle cruisers (somewhat more lightly armored

than the battleships denoted BB), and belonged to the USA.

### Why Relations?

- Database industry uses relations as the most important model for representing data.
- The set operations form the basis for database query languages such as SQL that are used to manipulate these databases.
- The supplanting of earlier, ad-hoc database systems by systems based on formal models and ideas is probably the greatest single example of how theory leads to improved practice and ultimately to commercial success.

# Dictionary Operations on General Relations

We may describe subsets of tuples by selection conditions indicating for each column either

- 1. A specific value the tuples must have, or
- 2. No restriction, indicated by a \*.
- The generalized *lookup* operator takes a selection condition C and a relation R to which it is applied. It returns the relation of all those tuples in R that match C.

**Example:** Let C be the selection condition (\*,\*,10,14,\*,\*). Then lookup(C,Classes) asks for those classes of ships with 10 14-inch guns. It produces:

Class	Weight	Guns	Caliber	Туре	Country
King George V	38000	10	14	BB	Gt. Br.
Nevada	29000	10	14	BB	USA
New York	27000	10	14	BB	USA

• Deletion also uses a selection condition and a relation, from which it deletes all the tuples matching the condition.

**Example:** delete(C, Classes) would delete the above 3 tuples from relation Classes.

• Insertion only makes sense if all components of the tuple are specified; i.e., no \*'s.

Example: insert((Vittorio Veneto, 41000, 9, 15, BB, Italy), Classes) adds to relation Classes the single tuple indicated.

# Efficiency of Access

The data structure used to store a relation influences greatly the time it takes to perform a lookup or other operation.

**Example:** Consider relation Course-Student, whose pairs are a course and a student taking that course.

- If we build a hash table with domain = Course, we get efficiency for conditions like (CS109A, \*).
- But no help for a condition like (\*, Alan Hu).
  - □ We must search all the buckets.

### Keys

An attribute (or set of attributes) is a key for relation R if we do not expect to find more than one tuple of R that agree in the key attribute(s).

- Important: keyness depends on our notion of what might be in R at some time.
  - ☐ It is insufficient that no tuples agree in a set of attributes today, if the relation could legitimately have two agreeing tuples sometime.

**Example:** For Classes, we expect that Class is a key, since there are unlikely to be two classes with the same name.

However, two classes from different countries
might bear the same name, so perhaps {Class,
Country} is a safer choice of key.

# Why Keys?

• Useful choice as the domain in a data structure.

- □ E.g., a hash table with a key as domain need not send many tuples to the same bucket for having the same domain value.
- ☐ In contrast, Course-Student has a nonkey domain and must hash all pairs with a course like CS109A to the same bucket.
