MLISP

by

David Canfield Smith

ABSTRACT1   MLISP Is a   high level list-processing and symbol-
manipulation language based o n the programming language
LISP, MLISP programs are translated Into LISP programs and
then executed or compiled, MLISP exists for two purposes:
(1) t o facilitate the writing and understanding of LISP
programs; (2) to remedy certain Important deficiencies In
the list-processing ability of LISP,

PAGE

. INTRODUCTION - SECTION 1

Most programming languages are designed with the idea that the syntax should be structured to produce efficient code for the computer. Fortran and Algol are outstanding examples. Yet, it is apparent that HUMANS spend more time with any given Program than the COMPUTER. Therefore, it has been our intention to construct a language which is as transparently clear and understandable to a HUMAN BEING as possible. Considerable effort has been spent to make the syntax concise and uncluttered. It reduces the number of parentheses required by LISP, introduces a more mnemonic and natural notation, clarifies the flow of control and permits comments. some "meta-expressions" are added to improve the list-processing power of LISP. Strings and string manipulation features, particularly useful for input/output, are included. In addition, a substantial amount of rsdundanoy has been built into the language, permitting the programmer to choose the most natural way of writing routines from a variety of possibilities.

LISP is a list-processing and symbol-manipulation language created at MIT by John McCarthy and his students (McCarthy, 1965). The outstanding feature8 of LISP are: (1) the simplest and most elegant ayntax of any language in existence, (2) high-level symbol manipulation capabilities, (3) an efficient set of list-processing primitives, and (4) an easily-usable power of recursion. Furthermore, LISP automatically handles all internal storage management, freeing the user to concentrate on problem solving. This is the single most important improvement over the other major list-processing language, IPL-V. LISP has found applications in many important artificial intelligence investigations, including symbolic mathmatics, natural-language handling, theorem proving and logic.

Unfortunately, there are several important weaknesses in LISP. Anyone who has attempted to understand a LISP program written by another programmer tar even by himself a month earlier) quickly becomes aware of several difficulties:

A. The flow of control is very difficult to follow. In fact, it is about as difficult to follow as machine language or Fortran. This makes understanding the purpose of routines(i.e. what do they do?) difficult. Since comments are not usually permitted, the programmer is unable to provide written assistance.

B. An inordinate amount of time must be spent ba ancing parentheses, whether in writing a LISP program or trying to understand one. It is frequently difficult to determine where one expression ends and another begins. Formatting utility routines ("pretty-print") help but every LISP programmer knows the dubious pleasure of laboriously matching left and right parentheses in a function, when all he knows is that one is missing somewhere!:

c. The notation of LISP (prefix notatlon for functions, parentheses around all functions and arguments, etc.), while uniform

from a logician's point of view, is far from the most natural or mnemonic for a language, This clumsy notation also makes It difficult to understand LISP programs, Since MLISP programs are translated Into LISP s-expressions, all of the elegance of LISP Is preserved at the translated level; but the unpleasant aspects at the surface level are eliminated,

D, There are important omissions In the list-processing capabilities of LISP, Those are somewhat remedied by the MLISP "meta-expressions", expressions which have no direct LISP correspondence but instead are translated Into sequences of LISP Instructtons, The MLISP meta-expressions are the FOR expression, WHILE expression, UNTIL expression, Index expression, assignment expression, and vector operations, The particular deficiency each of these attempts to overcome Is discussed In the subsection of SECTION 3 describing the meta-expression In detail,

MLISP was written at Stanford University by Horace Enea for the IBM 360/67 (Enea, 1968), The present author has Implemented MLISP on the POP-10 time-shared computer, He has rewrittan the translator, expanded and simplified the syntax, and Improved the run-time routines, All of the changes and additions are Intended either to make the language more readable and understandable or to make It more powerful,

MLISP programs are first translated into LISP programs, and then these are passed to the LISP interpreter or compiler, As Its name Implies, MLISP la a "meta-LISP" language; MLISP programs may be viewed as a superstructure over the underlying LISP processor, All of the underlying LISP functionsareavailable to MLISP programs, In addltlon to several powerful MLISP run-time routines, the purpose of having such a superstructure Is to Improve the readability and writeability o fLISP, long (In)famous for Its obscurity, Since LISP Is one of the most elegant and powerful symbol-manipulation languages (but not one of the most readable), It seems appropriate to try to facilitate the use of It,

MLISP has been running for several years on the Stanford PDP-10 time-shared computer, It has been distributed to the DEC User Services Group (DECUS), The MLISP translator and run-time routines are themselves compiled LISP programs, The Stanford version runs under the Stanford LISP 1,6 system (Quam, 1969), Some effort has been made to keep the translator as machine Independent as possible; In theory MLISP could be Implemented on any machine with a working LISP system by making only minor changes, The one probable exception to this Is the MLISP scanner; to enable scanning (where most of the time Is spent) to be as efficient as possible, the translator uses machine language scanning routines, While these routine9 have greatly Increased translation speed (MLISP now translates at a rate of 3000-5000 lines per minute,), their use means that someone wishing

to implement MLISP on a system without LISP 1.6 will have to use an
● aulvqent scanner package. For this reason, a whole section of this
manual (SECTION 7) is devoted to presenting an equivalent scanner.

While LISP was created with the goal of being machine independent, it
has turned out that most LISP systems have unique features. The
situation is so difficult that Anthony Hearn has attempted to define
"a uniform subset of LISP 1.5 capable of assembly under a wide range
of existing compilers and interpreters," called STANDARD LISP (Hearn,
1969). MLISP helps to alleviate this situation by introducing
another level of machine independence: to implement MLISP on a given
LISP system, one changes the underlying translator rather than the
surface syntax. Dr. Hearn has also constructed an MLISP-like
language called REDUCE (HEARN, 1970).

, SYNTAX - SECTION 2.1

The complete MLISP syntax is contained In the following section. Several sets of meta-symbols are used to simplify the presentation of the syntax:

(1) <> - **ANGLED BRACKETS** enclose non-terminal symbols.

(2) () - **BRACES** enclose optional elements; i.e. the elements inside tray or may not be present.

(3) ()* - These special meta-symbols enclose optional elements which may bo present 0 or more times (i.e. the enclosed elements need not be present, but there is no limit to the number of times they may occur).

(4) <> - **"HORSE SHOES"** enclose alternative elements, which are separated by commas. The user may select any one of the enclosed elements to form a legal syntactic expression.

(5) The BNF symbols ::= and |are used to define syntax elements. The left-hand side of the ::= symbol Is the syntax element being defined; the right-hand side Is Its definition. The vertical bar (|)Is used to indicate alternative definitions.

(6) All other symbols stand for themselves.

There are **several features** of MLISP that am **not** explicitly In the syntax:
(a) **IGNORED CHARACTERS** - All spaces, carriage returns, line feeds, form feeds, tabs, vertloal tabs, and altmodes are Ignored by the scanner.

(b) **COMMENTS** - Any sequence of characters enclosed between percent signs (%) Is taken to be a comment. The scanner Ignores comments, considering them to be completely non-existent; ABC%<anything>%DEF Is the same as ABCDEF as far as the soannsr Is concerned. **NOTE:** the comment symbol(%) may not be used In any other capacity than to start or end a comment!! The MLISP-defined atom **PERCENT** (value is %) facilitates dealing with the percent sign In other capacities.

The user should note that there are no "statements" in MLISP; everything returns a value, even FOR-loops, WHILE-loops, etc. Therefore, all major syntactic entities are "expressions".

DISCLAIMER: For reasons of simplicity, thesyntax presented below is slightly different from the one the translator actually uses. The only difference is that infix operators do not *all* have the same precedence. Instead they are organized into a precedence (hierarchy) system. Example:

        A + B * C - D CONS L

Is the same *as*

        ((A + (B * C)) - D)   CONS   L.

From this it may be seen that * takes precedence over + and -, and all three take precedence over CONS. The complete precedence system is explained in the section on infix operators (SECTION 3.3). Giving infix operators different precedences helps to cut down on the number of parentheses needed.

. SYNTAX - SECTION 2.2

```
<program>                 ::= <expression> .

. SEMANTICS -SECTION 3

This section presents the meaning of each of the elements in the syntax. First the syntactic parts about to be explained are listed. than their mranlng is explained In detail. Finally, a series of expamples illustrates them, and in many cases their actual LISp translations e rl) given.

It is assumed that the user has a working knowledge of LISP. If not, Welssman's **PRIMER** (Welssman, 1967) provides a good tutorial. McCarthy's **PROGRAMMER'S MANUAL** (McCarthy, 1965) la the standard reference manual. In addition, the user should familiarize himself with the manual for his LISP system, since, as was pointed out, LISP systems may vary from computer to computer.

In this section the symbol "→" means "is translated into".

, **SEMANTICS ▪ SECTION 3.1**

<program> ::= <expression> .

An MLISP program is an expression followed by a period. Usually the
program is a series of expressions enclosed in a BEGIN-END pair; i.e.
it is black. This permits more   than one   MLISP expression to b e
translated at the s a m e time, The translation of thr program gets
bound to the function **RESTART** aftertranslationhas been completed.
Example: if the MLISP program is

```
        BEGIN
            NEW Xi
            X ← READ();
            PRINTSTR("I JUST READ " CAT X);
        END,
```

then **RESTART** would be defined to be

```
        (DEFPROP RESTART
         (LAMBDA NIL
          (PROG (X)
                (SETQ x (READ))
                (PRINTSTR (CAT (QUOTE "I JUST REAR ") X))))
         EXPR)
```

Basically the **RESTART** function serves to give a name to thr main body
of   the program, so that the user can execute his program at any time
by call ing it. For example, typing (RESTART) to LISP would cause tho
above program to be executed.

'Any expression whose translation is NIL   (i.e. function definitions
and **DEFINE** expressions)   are   not included in the RESTART function;
only executable (non-NIL) expressionsare included. Example: if the
MLISP program is

```
        BEGIN
            NEW X,Y;
            EXPR MAX (X,Y);  If X ≥ Y THEN  X  ELSE  Y;
            EXPR TPRINT(X); TERPRI  PRINT  X;
            TPRINT MAX(X ← READ(),  Y ← READ());
        END ,
```

then **RESTART** would be defined to be

```
        (DEFPROP RESTART
         (LAMBDA NIL
          (PROG (X Y)
                (TPRINT (MAX (SETQ X (READ)) (SETQ  Y  (READ))))))
         EXPR)
```

, **SEMANTICS - SECTION 3.2**

<expression> ::= <simple_expression> (<infix_operator><simple_expression>)*

An expression is one or more simple expressions separated by infix operators:

<simple_expression>
<simple_expression> <infix_operator> <simple_expression>
<simple_expression> <infix_operator> <simple_expression>
       <infix_operator> <simple_expression>
...

From this description, it appears that all infix operators have the same precedence. However, several often-used LISP functions have been given different precedences from the others. This often enables one to eliminate parentheses that would be necessary to group the terms in an expression. The precedences have been chosen to be as natural and useful to the LISP programmer as possible. Example:

       A+B*C = D/E | X=Y & Z=W

is the same as

       ((A + (B*C)) = D) | ((X=Y) & (Z=W)),

but the former is far more readable than the latter. The precedence system used is explained in detail in the following section on infix operators (SECTION 3.3).

Examples of expressions:

A	→	A
(A)	→	A
¬A	→	(NOT A)
'A	→	(QUOTE A)
"A"	→	(QUOTE "A")
<A>	→	(LIST A)
16	→	16
123.45E+10	→	1.2345E12
OCTAL 100	→	64 (decimal)
"THIS IS A STRING."	→	(QUOTE "THIS IS A STRING.")
"ANOTHER " CAT "STRING"	→	(CAT (QUOTE "ANOTHER ") (QUOTE "STRING"))
'(A (B.C) D)	→	(QUOTE (A (B.C) D))
<'A,'(B.C),'D>	→	(LIST (QUOTE A) (QUOTE (B.C)) (QUOTE D))

```

, SEMANTICS • SECTION 3,3

```
<Infix_operator>    !!=   <regular_infix>
                     |    <vector_infix>

<regular_infix>     !!=   ⊂*, /, +, -, ↑, ↓, @, ≡, ≠, ≤, ≥, ∈, &, ∧, |, ∨⊃
                     |    <identifier>

<vector_infix>      !!=   <regular_infix> •
```

A n infix operator is either a regular infix or a vector infix. A regular infix is any of the symbols listed, or an identifier which is the name of a function taking two arguments. A vector infix is a regular infix followed by the vector indicator (•).

(A) Regular Infixes

The normal L I S P w a y of writing function calls is   the   "prefix
notation,"   the   function **name** occuring first followed b y   its
arguments:
        PLUS(A,B),
MLISP permits functions called with two arguments to be written In
the "Infix notation,"   t h e   function n a m e occuring between   the
arguments:
        A PLUS 8,
In addition, certain   commonly-used LISP and MLISP functions have been
given abbreviations:
        A * B,
Below la a complete list of these abbreviations, The user can define
abbreviations for his own functions, or change the MLISP-defined
ones, by using the **DEFINE** expression(SECTION3,7),

Abbreviation	Function	
*	**TIMES**	
/	**QUOTIENT**	
+	PLUS	(May be used a@ a prefix,)
-	DIFFERENCE	(MINUS If used as a prefix)
↑	PRELIST	(see SECTION 5,2)
↓	SUFLIST	(see SECTION 5,2)
@	APPEND	
=	**EQUAL**	
≠	NEQUAL	(see **SECTION** 5,2)
≤	LEQUAL	(see **SECTION** 5,2)
≥	GEQUAL	(see **SECTION** 5,2)
∈	MEMBER	
&	AND	
∧	**AND**	
ǀ	**OR**	
∨	**OR**	
¬	NOT	(This Is a prefix, not an Infix,)

Infix operators d o not all have the same precedence; some take
priority over others when expressions are parsed, Example:

        A + B * C - D / E

Is parsed:

        (A + (B * C)) - (D / E),

A precedence system for Infix operators has   been set up (a) to help
cut down on the number of parentheses needed; and (b) because most
programming languages have a precedence system, and so having one Is
more natural to a Programmer than not having one,

Listed below is the complete precedence system for infix operators in MLISP. Any function which does not appear explicitly in the table below will be assigned the default precedence and binding powers (unless the user assigns different ones with the DEFINE expression). For reference, the table below is also listed in **SECTION 2.5**.

Symbol	Function	Precedence	Binding Power Left	Right
*	TIMES	1	700	750
TIMES	TIMES	1	700	750
*TIMES	*TIMES	1	700	750
/	QUOTIENT	1	700	750
QUOTIENT	QUOTIENT	1	700	750
*QUO	*QUO	1	700	750
+	PLUS	2	600	650
PLUS	PLUS	2	600	650
*PLUS	*PLUS	2	600	650
-	DIFFERENCE	2	600	650
DIFFERENCE	DIFFERENCE	2	600	650
*DIF	*DIF	2	600	650
<default>		3	500	550
@	APPEND	4	450	400
APPEND	APPEND	4	450	400
*APPEND	*APPEND	4	450	400

GEQUAL	GEQUAL	5	300	350

¢	**MEMBER**	5	**300**	**350**
MEMBER	**MEMBER**	5	300	350
MEMQ	MEMQ	5	300	350
&	AND	6	200	230
A	**AND**	6	200	250
AND	AND	6	200	250
I	**OR**	7	**100**	150
v				
OR	OR OR	11	100 100	150 150

The reader has probably noticed that the last two columnr In this table are labled Binding Power - Left and Right, Basically, the "binding powers" of an infix operator are the strengths with which It "binds" or pulls on the elements to the left and right of It, The concept of bindlng powers is sufficient t o completely specify any precedence system, For example, consider:

A + 8 * C,

Both + and * are trying to attroh B as the second argument for the Ir functions (PLUS and TIMES), But the left bindlng power of * (700) Is greater than the right binding power of + (650), so this expression would be parsed:

A + (B * C),

As another example, suppose the user has defined a two-argument function MAX, Since MAX does not occur explicitly In the precedence system above, the default bindlng powers (500 and 550) are used. Then

A MAX B MAX C

is parsed:

(A MAX B) MAX C

since for default functions the right bindlng power Is greater than the left bindlng power, This Is also true for all other functions except those on precedence level 4, t h e s-expression building functions (APPEND, CONS, etc,), For a LISP user, It Is not only more natural but more efficient to have the assoofatlon of these functions go to the right:

4 C O N S B CONS C CONS NIL

Is parsed:

A CONS ⟨B **CONS** (C **CONS** NIL)).

The user should study the precedence system above. Parentheses may be used a t any time to alter the associations of the precedence system, but hopefully It has been constructed carefully enough s o that the user will seldom have to do this.

All user-defined infix functions normally get assigned the default binding powers. Note that this means that user-defined functions normal lytake precedence over some LISP and MLISP functions (those on preccfdence levels 4 - 7). However; the user can assign different binding powers to his functions, or even to the funotlona above, by means of the DEFINE expression (SECTION 3.7). With the DEFINE expression, he orn set up any Precedence system he choses.

The rationale for the precedence system:

1 *, TIMES, *TIMES   First come the arithmetic functions,
   /, QUOTIENT, *QUO   which operate only on numbers and
                               which yield only numerical values.

2 +, PLUS, *PLUS   As is natural, multiplication   and
   -, DIFFERENCE, *DIF   division   take   precedence   over
                               addition and subtraction.

3 all others   Then come all user-defined functions,
                               and all LISP and MLISP functions not
                               listed here explicitly.

4 @, APPEND, *APPEND, NCONC   These are followed by functions which
   CONS, XCONS   operate on s-expressions to build new
   CAT   s-expressions.

5 EQ   Of lower precedence are functions
   =, EQUAL   which operate on s-expressions, but
   ≠, NEQUAL   which yield only boolean values.
   ≤, LEQUAL, LESSP, *LESS
   ≥, GEQUAL, GREATERP, *GREAT
   ∈, MEMBER, MEMQ

6 &, ∧, AND   Of lowest precedence are functions
                               which operate only on boolean values,
                               and which yield only boolean values.

7 |, ∨, OR   As is natural,   OR has a lower
                               precedence than AND;   In fact OR has
                               the lowest precedence of   any
                               function.

In addition to infix operators, prefix operators and   the assignment
operator (←) have   also been implemented using binding powers. The
binding powers for prefixes are -1 and 1000; those for the assignment
operator ape $001 and 0,   These may be changed by the DEFINE
expression, They are listed only for reference; the use of prefixes
and assignment expressions is explained better by the syntax.

(B) Vector Infixes

Vector infixes are a very powerful MLISP concept. They provide a concise means of mapping functions onto one or two lists, a facility not readily available In LISP, They developed from the observation that lists may be regarded as any-dimensional vectors. The LISP system then becomes an infinite-dimensional vector space. Scalars In this vector apace are atoms. Vector infixes (and veotop prefixes) are a n attempt to define some primitive operations over this vector space, Basically vector Infixes are functions which are mapped onto their vector (list) arguments to yield a vector (list) o f results, much like a two-argument MAPCAR.

Suppose V = (v1, v2, ... vm) and W = (w1,w2, ... wn) are two vectors (i.e. lists), Addition of two vectors is accomplished by:

$$V +\bullet W = (v1+w1, v2+w2, ... vk+wk), \quad \text{where } k = min(m,n).$$

Multiplication by a scalar:

$$10 \ \ *\bullet \ v = (10*v1, 10*v2, ... 10*vm)$$
$$v \ *\bullet \ 10 = (v1*10, v2*10, ... vm*10)$$

Multiplication of two scalars:

$$10 \ *\bullet \ 20 = 10 * 20 = 200$$

To illustrate these vector primitives, we will use them to write the Euclidean Inner product:

$$V . W = \sum_{i=1}^{k}(vi + wi)$$

First observe that If we CONS the function PLUS onto a list of numbers, we get an executable expression:

'**PLUS CONS** '(1 2 3 4 5)   =   (**PLUS**   1 2 3 4 5),

Then:

EXPR INNERPROD (V,W); EVAL ('PLUS **CONS** V +• W)

is the desired Inner product function using vector operations, It Is worthwhile noting that we could also write:

```
EXPR  INNERPROD (V,W);
    BEGIN  NEW SUM;
        SUM + 0;
        FOR NEW v IN V FOR NEW w IN W DO SUM + SUM + (v+w);
        RETURN SUM
    END
```

or equivalently:

      EXPR INNERPROD(V,W);   FOR **NEW** v **IN V FOR NEW** w **IN** W; PLUS v+w

Vector operations, however, provide the most concise means of writing the function.

The next logical step in the development of vector operations is to permit virtually any two-argument LISP, MLISP or user-defined function to be used as a vector operator:

V *• W	=	(v1 * w1, v2 * w2,..., vk * wk)
V CONS. W	=	(v1 **CONS** w1, v2 **CONS** w2,..,vk **CONS** wk)
V FOO• W	=	(v1 FOO w1, v2 FOO w2,..., vk **FOO** wk)

where in each case $k = \min(\text{length } V, \text{length } W)$.

Note:
(a) The result of vector operations is a vector (i.e. list), unless
    both arguments are scalars (atoms),
(b) The length of the result vector is the shorter o f the lengths of
    the two vector arguments, or the length of the vector argument if
    the other argument is a scalar,

Following an infix operator by the vector indicator (•) does not change its precedence. In determining the parsing of an expression, the presence of absence of • is Ignored!

      A +• B +• C **CONS*** L

Is parsed exactly the same a8

      A + B + C CONS L,
namely.
      (A +• (B +• C)) CONS• L,

In addition to two-argument vector infixes, one-argument vector prefixes are also permitted. These are discussed In the following section on prefix operators (**SECTION 3,4**). Example:

      ATOM• '(A   B (C) D) = (T T NIL T),

Examples o f infix operators:

A + 10	→	**(PLUS A 10)**
A + 1	→	(ADD1 A)
A - 10	→	**(DIFFERENCE A 10)**

                                       = (JOHN_DOE JOHN_SMITH)

. SEMANTICS - SECTION 3,4

```
<prefix_operator>    ::=    <regular_prefix>
                     |      <vector_prefix>

<regular_prefix>     ;a+    c+, -, ~>
                     |      <identifier>

<vector_prefix>      ::=    <regular_prefix> .
```

4 prefixoperator|s ● 1thot a regular prefix or a vector prefix, A regular prefix is any of the symbols +, - o or ~, o or an identifier representing any one-argument functionwhich the MLISP translator knows about, A vector prefix is a regular prefix followed by the vector indicator (•),

Regular prefixes

The main purposes of prefixes are to clarify expressions and t o ● Jlnkat@ parentheses, NOT X isbetterthan NOT(X), though both are legal; and ~X is even better, The translator knows about all one-argument LISP and MLISP functions, In addition, the translator notes all one-argument EXPR's translated, Later o n in the program (i,e, after the function definition), that function may be used I ike any other prefix, Example: If the function definition
        EXPR FOO (X); TERPRI PRINT X
occurred In a program, then In the rest of the program following this definition It would be legal to treat FOO a8 a prefix.

This is one way that the translator can be made aware Of user-defined prefixes, Another way is to use the DEFINE expression (SECTION 3,7):
        DEFINE FOO PREFIX
has the effect of stating Co the translator that the function FOO, regardless of its definition (if any), will only have one argument In the rest of the program and so shouldbe treated as a prefix,

Vector prefixes

Vector prefixes are a very Interesting and very powerful extension of prefix operators, The concept of vector operations was explained in the preceeding section, The basic idea is that vector prefixes operate on not Just one, but on a whole list of arguments, and they return a whole list of values, The prefix operator is mapped onto the list, with the operator applied to each element in it, This enables many complexexpressions to be written concisely, Vector prefixes may also Operate on atoms (scalars) Instead of lists,

Examples of prefix operators:

+X	→	X
-X	→	(MINUS X)
¬X	→	(NOT X)
NOT X	→	(NOT X)
NOT(X)	=	(NOT X)
ATOM FOO(X,Y,Z + 10)	→	(ATOM (FOO X Y (PLUS Z 10)))
NULL CDR L	→	(NULL (CDR L))
TERPRI PRINT CAR L	→	(TERPRI (PRINT (CAR L)))
LENGTH L + 10	→	(PLUS (LENGTH L) 10)
¬A ∧ ¬B ∧ ¬C	→	(AND (NOT A) (NOT B) (NOT C))
NUMBERP X ∨ ¬ATOM X	→	(OR (NUMBERP X) (NOT (ATOM X)))
NOT ATOM X ← READ()	→	(NOT (ATOM (SETQ X (READ))))
NOT ATOM X & READ()	→	(AND (NOT (ATOM X)) (READ))
NOT ATOM X CONS READ()	→	(CONS (NOT (ATOM X)) (READ))

Vector prefixes:

Suppose L = (A B (C D) NIL E).

ATOM• L	=	(T T NIL T T)
NOT• ATOM. L	=	(NIL NIL T NIL NIL)

of a simple expression.

```
<block>               ::=  BEGIN
                              (<declaration> ;)*
                              (<expression> ;)*
                              (<expression>)
                           END

<declaration>         ::=  NEW <identifier_list>
                       |   SPECIAL <identifier_list>

<identifier_list>     ::=  <identifier> (, <identifier>)*
                       |   <empty>
```

A block is the reserved w o r d BEGIN, followed by any number of
declarations separated by semicolons (;), followed by any number of
expressions separated by semicolons, followed by the reserved word
END. The last expression need not have a aemicolon after it.   A
declaration is either of the reserved words **NEW** or **SPECIAL.** followed
by an identifier list.   An identifier l ist is any number of
identifiers (possibly none) separated by commas.

A block is translated into a PROG.   Any variables (identifiers)
declared using the **NEW** declaration become the PROGvariables. **Check**
your **LISP manual**   to see whether or not **PROC** variables are
automatically initialized to NIL in your version of LISP. The scope
of NEW variables is the scope of the PROG, i.e. until the matching
END.   **N E W** variables may also be declared SPECIAL. **Each** expression
following the declarations untilthe END becomes a statement in the
PROG.   There should be a semicolon after each expression, with the
● xocrptlon that the last semicolon is optional.   END closes o f f   the
PROG.

SPECIAL declarations are somewhat unique In that they have no
translation; instead they have an effect on the translator. A flag
for the **LISP** 1.6 compiler   Is put on the property list of each
variable declared sPECIAL,   Thisflagenables the compiler to compile
free variables and **global** variables correctly.

SPECIAL declarations have   the effect of declaring their variables
SPECIAL throughout the entire program, regardless of the physical
location of thedeclaration In the program. This **enables** the user to
mark variables **SPECIAL** wherever It is convenient to do so,   and
simultaneously prevents the compiler (and user) from getting confused

whenvariables are sometimesSPECIAL and sometimes not,   It Is a good
Idea to make SPECIAL variable names distinct from other variable
names as a way of keeping track of them, For example, an exclamation
mark (!) could be Included In each SPECIAL variable name; SPECIAL !A,
!B, !C, In general, the fewer variables that have to be declared
SPECIAL,   the better; the code for SPECIAL variables runs somewhat
slower than that for non-SPECIAL ones,

For the user's reference, the followingsection Is reproduced from
Quam's LISP 1,6 manual (Quam, 1969),

> In compiled functions, any variable which Is bound in a
> LAMBDA or PROG and has a free occurrence elsewhere must
> be declared SPECIAL,   CA variable Is said to have a free
> occurrence If It not bound In any LAMBDA or PROG
> containing the occurrence,]   [Also,] variables which are
> used In a functional context must be declared SPECIAL or
> else the compiler will mistake them for undefined EXPR's,

Similar restrictions hold for many other LISP compilers, It Is UP to
the user to make sure he understands fully the conventions fat
compiling In his LISP system, For the MLISP user, there Is one
further restriction: variables In the left-hand side of a
decomposition assignment expression (SECTION 3,111 must be declared
SPECIAL If the expressionIs to work correctly,

AS with PROG's, a value may be returned for a block by using the
RETURN function, Labels may be transferred to using the GO function;
labels are declared by following the label Immediately with a
semicolon (e.g, L;), not with a colon. However, the Iteration
"meta-expressions" descr I bed In following sections are to be much
recommended over labels and GO transfers,

Examples of blocks:

```
BEGIN                          →          (PROG NIL)
END

BEGIN                          →          (PROG NIL
L; X ← READ();                        L      (SETQ X (READ))
   IF X EQ Y THEN RETURN TRUE                (COND ((EQ X Y) (RETURN TRUE))
   ELSE PRINT <X,Y>;                                (T (PRINT (LIST X Y))))
   GO L;                                     (GO L))
END

BEGIN NEW X1,X2,X3;           →          (PROG (X1 X 2 X3)
    SPECIAL X3,Y,Z;                          (SETQ Z NIL)
    Z ← NIL;                                 (SETQ X I (READ))
    X1 ← READ();                             (SETQ X 2 (ADD1 (TIMES 10 X1)))
    X2   ← 10*X1 + 1;                        (COND
    IF FOO(X1,Y,Z) & X3=1 T H E N              ((AND (FOO X i Y Z) (EQUAL X 3 1))
        PRINTSTR("ANSWER=" CAT Y)              (PRINTSTR
    ELSE    X3 ← X2 + X1;                         (CAT (QUOTE "ANSWER=") Y)))
    RETURN X3                                 (T (SETQ X3 (PLUS X2 X1))))
END                                          (RETURN X3))

BEGIN                          →          (PROG NIL
    EXPR MAX (X,Y);                          (DEFPROP MAX
        IF X≥Y THEN X ELSE Y;                  (LAMBDA (XY)
                                               (COND ((GEQUAL X Y) X) (T Y)))
                                             EXPR)

    EXPR MAX-LIST(L,M);                      (DEFPROP MAX_LIST
        IF NULL L THEN M ELSE                  (LAMBDA (L M) (COND
        MAX LIST(CDR L,MAX(M,CAR L));          ((NULL L) M)
                                               (T (MAX_LIST (CDR L)
                                                       (MAX M (CAR L)))))))
                                             EXPR)

    PRINT MAX_LIST(READ(),0);                (PRINT (MAX_LIST (READ) 0)))
END
```

, **SEMANTICS** - SECTION 3,6

```
<function_definition>        ::=  EXPR, FEXPR, LEXPR, MACRO:, <identifier>
                                  ( <lambda_identifier_list> )) <expression>

<LAMBDA_expression>          ::=  LAMBDA
                                  ( <lambda_identifier_list> );<expression>

<lambda_identifier_list>     ::=  (SPECIAL) <identifier>
                                  (, (SPECIAL) <identifier>)*
                              |   <empty>
```

A function definition is one of the function types: EXPR, FEXPR,
LEXPR, MACRO, followed by an identifier (the name of the function),
followed by a LAMBDA variable list and **LAMBDA body, A LAMBDA**
expression Is essentially the same thing, being the reserved Word
LAMBDA followed by a **LAMBDA** variable list and **LAMBDA body,** A LAMBDA
identifier list Is any number of identifiers (possibly none)
separated by commas, Each identifier may be preceeded by the word
SPECIAL, This and the **SPECIAL** declaration In blocks are the two ways
the user may declare variables to be SPECIAL, (**SECTION** 3,5 discusses
SPECIAL variables,)

When the MLISP translator encounters a function definition, the
following three steps occur:
(1) The complete function definition Is translated,

(2) The function Is then Immediately defined (I,e, the definition Is
    carried out), without waiting for the rest of the program to be
    translated,

(3) **NIL Is returned as** the translation for the expression,

Note that since step (2) Is carried out In the middle of the
translation of the program, the user might accidentally redefine some
LISP or MLISP **function** that would cause the rest of his **program** to be
translated Incorrectly, To guard against this, each function name Is
first checked to see If It already has a function definition of any
type) If It does, a warning message Is printed, If this happens,
change the name of the function and recompile the program.

Usually a program consists of a **BEGIN-END** pair enclosing a series of
function definitions and other expressions, Function definitions are
not executable at run time) their effect occurs at translation time,
In step (2) above, As step (3) states, NIL will be returned as the
translation for function definitions, All exectuable expressions
will have non-NIL translations, In translating a program, all NIL
translations are thrown out and only non-NIL ones retained,

Examples of function definitions:

EXPR NOTHING()； PRINTSTR " T H I S ISN'T MUCH OF A FUNCTION"；

EXPR REV(L)；   IF NULL L THEN NIL ELSE REV(CDR L)@<CAR L>；

FEXPR OPEN(X)；   EVAL <'INPUT,'DSK:,CAR X>；

MACRO NOT_MEMBER(X)；   <'NOT, <'MEMBER,X[2],X[3]>>；

EXPR FOOBAZ(X, SPECIAL Y)；
    BEGIN
        NEW A；
        IF X = REV(X) THEN A ← y
        ELSE BEGIN
            OPEN(FOO)；
            NOTHING()；
            CLOSE(FOO);
        END；
        RETURN <A, REV(A)>；
    END；

EXPR INNER_PRODUCT(V,W)；EVAL ('PLUS CONS V +●W)；
    % This takes the inner product o f t w o vectors (lists). %

EXPR INNER_PRODUCT(V,W)；   FOR   NEW v IN V FOR   NEW w IN W；PLUS v+w；
    · % So does this. %

Examples of LAMBDA expressions!

ASSume that "F00" represents a function which has bean defined to be the same as the LAMBDA expression In each of the following examples,

EXAMPLE 1,

mlisp: MAPCAR(FUNCTION(LAMBDA (X); X CONS NIL), '(A B C))

lisp: (MAPCAR (FUNCTION (LAMBDA (X) (CONS X NIL))) (QUOTE (A B C)))

equivalently: MAPCAR(FUNCTION(FOO), '(A B C),

EXAMPLE 2,

mlisp: LAMBDA (X,Y);
              IF X EQ Y THEN PRINTSTR "THEY ARE THE SAME" ELSE
              IF NOT ATOM X THEN PRINTSTR "FIRST IS NOT AN ATOM"
              ELSE PRINTSTR("X =" CAT X);
         (READ(), READ())

I lisp: ((LAMBDA (X Y)
            (COND
            ((EQ X y) (PRINTSTR (QUOTE "THEy ARE THE SAME")))
            ((NOT (ATOM X)) (PRINTSTR (QUOTE "FIRST IS NOT AN ATOM')))
            (T (PRINTSTR (CAT (QUOTE "X =") X)))))
           (READ)
           (READ))

equivalently: FOO(READ(), READ())

EXAMPLE 3,

mlisp: LAMBDA (X,Y,SPECIAL Q);
            LAMBDA (Z);
                IF FOO(X) THEN PRINT Z ELSE PRINT Q;
            (<X,Y>);
         (A,B+1, NIL)

lisp: ((LAMBDA (X Y Q)
            ((LAMBDA (Z) (COND ((FOO X) (PRINT Z)) (T (PRINT Q)))) (LIST X Y)))
           A
           (ADD1 B)
           NIL)

equivalently: FOO(A, B+1, NIL)

, **SEMANTICS - SECTION 3.7**

```
<DEFINE_expression>     ::=  DEFINE <DEFINE_clause> (, <DEFINE_clause>)*

<DEFINE_clause>         ::=  <DEFINE_symbol> PREFIX
                        |    <DEFINE_symbol> (PREFIX) <alternate_name>
                        |    <DEFINE_symbol> (pREFIX) (<alternate_name>)
                                <integer> <integer>

<DEFINE_symbol>         ::=  <identifier>
                        |    <any charactsr except" or %>

<alternate_name>        ::=  <identifier>
                        |    <any character except ", %, ) Or ,>
```

A OEFINE expression is onr or more DEFINE clauses separated b y
commas, A OEFINE clause is an identifier or any character except "
or % (the DEFINE symbol), followed by any or all oft (1) ths word
PREFIX, (2) an alternate name (abbreviation) for the DEFINE symbol,
and (3) two integers representing left and right binding powers for
the DEFINE symbol, A n alternate name is an identifier or a n y
character except ", %, semicolon (;) or comma (,),

The OEFINE ● xpreaslon provides a versatile means of communicating
with the MLISP translator, As with function definitions, the
translation of OEFINE expressions is NIL, Instead of a translation,
the DEFINE expression has an effect on the translator. The effect is
to assign certain properties to the OEFINC symbol which the
translator will make uss of In the rest of the program, The DEFINE
expression will be explained by examples,

Examples o f DEFINE expressions:

(1) DEFINE FOO **PREFIX**

This Informs the translator that hereafter In the Program the
function FOO is to be treated like a prefix (SECTION 3,4), This
means that FOO may be used without parentheses around Its argument,
and It may be used as a vsotor operator, Only identifiers which are
the names of one-argument functions should be defined to be prefixes.

(2) **DEFINE UNION u**

This Informs the translator that ths symbol ᵁ is to bs considered as
an abbreviation for the function UNION, After this DEFINE expression
has been translated, whenever the scanner encounters u, l f will

Immediately convert it to UNION. The effect of writing u will be exactly the same as if UNION had been written. The alternate name may be an identifier:

DEFINE CAR a

would convert every subsequent occurrence of a into CAR. Also, the DEFINE symbol itself may be a special character:

DEFINE ; ,

would translate all commas in   the   rest   of   the program   into semicolons.

DEFINE ; STOP

would translate every subsequent occurrence of the word STOP fnto a semicolon. to illustrate this, consider the following example:

```
BEGIN                          →      (PROG NIL
    DEFINE CAR a, CDR d, NULL n,
        IF if, THEN →, ELSE else;
                                     (DEFPROP rev
    EXPR rev (l);                     (LAMBDA (l)
        if n I → nil                   (COND((NULLl) NIL)
        else rev(d l) @ <a l>;                (T (APPEND (rev (CDR l))
END                                                    (LIST (CAR l)))))))
                                     EXPR))
```

(3) DEFINE UNION 360 370

This specifies that the   left   and   right binding powers   for   the function UNION are   to be 360 and 370 respectively. Binding powers are explained in the section   o n   infix operators (SECTION 3.3).   The value 3   above would give UNION a precedence of   between 4 and 5 in the precedence system for   infix operators (o.f. SECTION 3.3).   Only identifiers   representing   one-   and   two-argument functions (prefixes and infixes) should be given binding powers.

(4) D E F I N E UNION u 360 370

This   defines u   to   be an abbreviation for UNION and simultaneously sets up left and right binding powers for UNION.

(5) DEFINE FOO PREFIX α

This specifies that the function FOO is to be treated as a prefix, and that the symbol a is to be considered an abbreviation for it.

(6) OEFINE NOT PREFIX - -1 1000

This specifies that the function NOT is to be treated as a prefix, that the symbol - is to be considered an abbreviation for it, and that its left and right binding powers are to be -1 and 1000 respectively. The equivalent of this expression has already been executed for all one-argument LISP and MLISP functions.

(7) DEFINE UNION u 360 370, INTERSECTION ∩ 380 390, RETURN PREFIX -1 0;

After this DEFINE expression has been translated,

     RETURN A ● B u C ● D ∩ E ● F

would bo translated

(RETURN (UNION (APPEND A B) (INTERSECTION (APPEND C D)(APPENDEF))))),

exactly as if it had been written

     RETURN ((A ● B) u ((C ● D) ∩ (E ● F))).

UNION is given lower binding powers than INTERSECTION, and both of them have lower binding powers than the 400 and 450 binding powers of (●) APPEND (SECTION 2,5). Seting the right binding power of RETURN to 0 insures that an entire expression (In this case: A ● B u C ∩ D ● E) will be translated as its argument, rather than just a simple expression as would normally be the case (since RETURN is a prefix). This is because all binding powers in MLISP are larger than 0; therefore, all infix operators will bind up their arguments before RETURN does. In fact, anything with a right binding Power of 0 will gobble ✝℞ ● vowthbg until the next expression-stopper (reserved word, ")", "1", etc.).

, **SEMANTICS** - SECTION 3.8

<IF_expression>   ::=   IF <expression>
                          THEN <expression> (ALSO <expression>)*
                          (ELSE <expression> (ALSO <expression>)*)

An IF(or conditional) expression is the reserved word IF, followed
by any expression,   followed by the reserved word THEN end another
● xores!Uon, optionally followed by any number of ALSO clauses.   This
Is optionally followed by the reserved word ELSE and a third
expression, again optionally followed by any number of ALSO clauses.
An ALSO clause is the reserved word ALSO followed by any expression.

Conditional expressions get translated into **LISP** COND's,   In LISP 1.6
there may be more than one expression after the predicate;example:

          (COND (P1 E1) (P2 **E2** E3) (P3 **E4** E5 E6))

Is a legal LISP 1.6 conditional expression. **Where there is** more **than**
one expression, the expressions are evaluated from left to right; the
value of the last one becomes the value of the COND.

In the following, E1, E2, E3 ... represent any expressions.

IF **E1** **THEN** **E2**   →   (COND (E1 E2) (T NIL))

IF E1 THEN E2 **ELSE** E3   .   (COND **(E1** E2) (T E3))

IF E1 **THEN** E2 ALSO E3   →   (COND (E1 **E2** E3) (T **E4** E5 E6))
ELSE E 4 ALSO E 5 ALSO E6

IF E1 **THEN** **E2** **ELSE**   →   (COND (E1 E2) (E3 E4)(T E5))
IF E3 **THEN** E4 **ELSE** E5

Nesting of conditionals is permitted to any degree of complexity.
Each ELSE term Is matched UP with the nearest preceeding THEN, unless
parentheses are used to group the terms differently.

IF E1 **THEN**   →   (COND (E1 (COND (E2 E3) (T E4)))
     IF E2 THEN E3 **ELSE** E4   (T NIL))

IF E1 **THEN**   →   (COND (E1 (COND (E2 E3) (T **NIL)))**
     (IF E2 **THEN** E3)   (T E4))
ELSE E4

IF E1 **THEN**   →   ´   (COND **(E1** (COND (E2 E3) (T E4)))
     IF E2 **THEN** E3 **ELSE** E4   (T E5))
ELSE **E5**

Examples of IF expressions:

IF X = 10   THEN   PRINT Y .   (COND((EQUAL X 10)(PRINT Y))(T NIL))

IF X ≠ 10   THEN   PRINT   y .   (CONO((NEQUAL X 10)(PRINT Y))
ELSE PRINT Z   (T (PRINT Z)))

                                      (COND
IF A & B & C & D   THEN   →   ((AND   A   B C D)
    IF X∈L THEN PRINT 'MATCH   (COND ((MEMBER X L)(PRINT (QUOTE MATCH))
    ELSE PRINT 'NO_MATCH   (T(PRINT (QUOTE NO_MATCH)))))
ELSE IF FOO(A,B) & ¬C THEN   ((AND(FOO A B)(NOT C))
    IF <X> ∈ L THEN PRINT T   (COND((MEMBER (LIST X)L)(PRINT T))
    ELSE PRINT NIL   (T (PRINT NIL))))
ELSE PRINT 'OH WELL   (T (PRINT (QUOTE OH_WELL)))))

IF X ≤ 100   THEN   →   (COND
    Y ← 2*X ALSO   GO L   ((LEQUAL X 100)(SETQ Y (TIMES 2 X))(GO L
ELSE Y←X+1 ALSO RETURN <X,Y>   (T(SETQ Y (ADD1 X))(RETURN (LIST X Y)))))

. SEMANTICS - **SECTION** 3.9

```
<FOR_expression>   ::=   <FOR_clause> (<FOR_clause)*
                         <DO, COLLECT, ; <identifier>> <expression>
                         (UNTIL <expression>)

<FOR_clause>       ::=   FOR (NEW) <identifier> <IN, ON> <expression>
                    |    FOR (NEW) <identifier>    ←      <expression>
                         TO <expression> (BY <expression>)
```

A **FOR** expression is any number of FOR clauses, followed by the
reserved word DO, the reserved word COLLECT, or a semicolon (;)
together with an identifier which is a two-argument function name.
This is followed by an ● ⊠●①□𝕞⁺⁺●□■ (the "body" of the FOR-loop), which
is optionally followed by the reserved word **UNTIL** and another
expression. A FOR clause is the reserved word **FOR**, optionally
followed by the reserved word **NEW** followed by an identifier (the
control variable), and followed by either: (a) the reserved word IN
or the reserved word ON, and an expression which evalutes to a list
(possibly NIL), or (b) a left arrow (←), followed by an expression
which evaluates to a number (the lower limit), followed by the
reserved word **TO** and another expression which evaluates to a number
(the upper limit). This is optionally followed by the reserved Word
BY and a third expression which evaluate8 to a number (the
increment).

The **FOR** expression (FOR-loop) I8 the most powerful meta-expression in
MLISP. It is designed to facilitate dealing with individual elements
in lists. The MLISP **FOR** expression carries the development of LISP's
MAPLIST and MAPCAR functions to their logical conclusion. Extensive
work has gone into the design and implementation of **FOR** expressions.
Used **thoughtfully**, they can greatly simplify manipulating lists. The
FOR expression is not just one, but many expressions; there is an
unbounded number of possible expressions that may be built up from
its syntax,

FOR expressions provide the ability to:
(A) **Step** through a list, dealing with each element in it individually
    (use IN).

(B) **Step** through a list, dealing with the whole list, the CDR of it,
     the CDDR of **It**, the CDDDR of it, etc. (use **ON**),

(C) Step **through a numerical range** (e.g. from 1 to 10) using any
    numerical **Increment** (use ←). There are no restrictions on the
    numbers **Involved** (lower limit, upper limit, Increment),

(D) **Step** through any number of lists and/or numerical ranges in
    parallel (use more than one FOR clause),

(E) Make the controlvarlabies local to **the body** of **the** FOR-lobp (use
NEW or to preserve theirvalues when the FOR-loop exits.
Control varlablrs should bespecified to be NEW whenever
possible, because the LISP code for NEW variables is more
efficient. Unless you are interested In the value of a control
variable after **the FOR-loop** exits, declare It NEW,

(F) Control the value returned by the FOR expression. The value
usingDOisthe value of the FOR-loop body the last time through
the loop; the value with COLLECT is a list formed by APPEND'Ing
together the values of the FOR-loop body each time through the
loop. Alternatively, any two-argument function may be used to
generate a FOR-exppression value: the first time through the
loop, the value of the FOR-loop body becomes the value of the
loop; each succeeding time through, the two-argument function is
applied to the previous value of **the loop and to the current
value of the** FOR-loop **body** to yield a new value for the loop.

(G)Terminate   ●   xeo&lon of **the loop at any** time (use UNTIL),

Example:

FOR NEW I IN X●Y FOR N●1 TO 10 BY 2 DO PRINT <N,I> UNTIL I EQ 'STOP

In this example, "FOR NEW I IN X●Y" rnd "FOR N●1 TO 10 BY 2" ape "FOR
clauses". I and N are "control variables", Iis "local" to the body
of the FOR-loop by virtue of its being declared NEW;Nis not local.
The expression "X●Y" {APPEND X Y) should evaluate to a list; I will
step through that list, being set to the CARof It, the CADR Of It,
the CADDR of I t, etc. The control variable N steps through a
numerical range (1-10) In increments of 2, The ● xproslrlon "PRINT
<I,N>" is the "body" of the FOR-loop. The UNTIL condition is "IEQ
'STOP", Since DO is used, the value of the FOR-loop Is the value of
"PRINT <I,N>" the last time It was executed,

The execution of FOR expressions proceeds as follows:
(1) The list or numerical range for each FOR clause Is checked, If
any list Ia NIL, or If any numerical range Ia exhausted, then the
FOR-loop exits returning Its current value (initially NIL).
Before ● xlttnQ, eaoh clause Is examined, If any olause ha8 a
control variable whfoh was deolared NEW, that control variable la
reset to the value It had when the loop was entered, If any
olause has a controlvariablewhioh wa8 not deolared NEW, and If
the list or range for that olause Is exhausted, then that control
variable Is set to NIL, Otherwise, the control variable Is left
set to the value It ha-d the last time through the loop; this may
be useful for determining which lists or ranges were exhausted,
and how many times the loop was executed.

A numerical range is said to be "exhausted" if (a) the increment is positive and the lower limit > tha upper limit, or (b) the increment is negative and the lower limit < the upper limit. An increment of 0 is, of course, illegal,

(2) Next, each control variable is assigned a value. This value is: (a) the CAR of its list if IN is used, (b) the entire list if ON is used, or (c) the lower limit if a numerical range is used.

(3) Then the body of the FOR-loop is executed, and a value is computed for the loop as explained in (F) above,

(4) Finally, the UNTIL expression (if any) is evaluated. If its value is true, the FOR-loop exits immediately. No control variables are reset except the ones declared NEW, which are set to the valuer they had when the loop was entered. Thus all non-NEW control variables will remain set to the values they had when the UNTIL condition became true. This is sometimes useful for testing how many times the loop was executed, and for determining the cause of termination. Example: In
    FOR I IN L DO PRINT I UNTIL I EQ 'STOP,
when the loop exits I will be set to NIL if it got all tho way through the list L without encountering the atom STOP; otherwise it will be set to STOP,

(5) If the UNTIL expression was false (or non-existent), the lists and numerical ranges are advanced as follows: (a) each list is set to the CDR of itself; (b) In each numerical range, the increment is added to the lower limit to yield a new lower limit.

(6) Then step (1) is executed again,

Continuing the example above, suppose X = '(A B C) and Y = '(D); then executing:

FOR NEW I IN X@Y FOR N=1 TO 10 BY 2 DO PRINT <N,I> UNTIL I EQ 'STOP

would
(a) print   (1 A)
                 (3 B)
                 (5 C)
                 (7 D)

(b) return a value of (7 D), and

(c) leave N set to 7,

The F O R expression

FOR   NEW   I I N X ● Y FOR N ← 1 TO 10 BY 2 DO   PRINT   <N, I>   UNTIL   I EQ 'STOP

Is equivalent t   o the following block:

```
        BEGIN    NEW    V, L1, L2, I;
            L1 ← X ● Y;
            L2 ← 1;

    LOOP; I F N U L L L1 I L2 GREATERP 1 0 THEN GO EXIT;
            I ← CAR L1;
            N ← L2;
            V ← PRINT <N, I>;
            IF I EQ 'STOP THEN RETURN V;
            LI ← C D R L1;
            L2 ← L2 + 2;
            GO LOOP;

    EXIT; IF NULL L2 THEN N ← NIL;
            RETURN V;
        END;
```

Examples of FOR expressions: Suppose 1. = '(A (B,C) D),

FOR NEW I IN L DO PRINT I   would print   A
                                                                       (B,C)
                                                                       D
                                                    and return D

FOR   I IN L DO PRINT I   would print   A
                                                                       (B,C)
                                                                       D
                                                    set I to NIL
                                                    and return D

FOR NEW I ON L DO PRINT I   would print   (A (B,C) D)
                                                                       ((B,C) D)
                                                                       (D)
                                                    and return   (D)

FOR NEW I I N L COLLECT P R I N T <I>   would print   (A)
                                                                       ((B,C))
                                                                       (D)
                                                    and return   (A (B,C) D)

FOR I IN L COLLECT PRINT <<I>>   would print   ((A))
                                                                       (((B,C))
                                                                       ((D))
                                                    set I to NIL
                                                    and return   ((A) ((B,C)) (D))

FOR NW I ON L COLLECT PRINT I   would print   (A (B,C) D)
                                                                       ((B,C) D)
                                                                       (D)
                                                    and return   (A (B,C) D (B,C) D D)

FOR NEW I ON L ; APPEND PRINT I   would have exactly the same effect
                                                    as the preceeding FOR expression.

FOR I **IN** **L** **DO** **PRINT** I **UNTIL** **NOT** **ATOM** I   would print   A

DECK ←
   FOR NEW SUIT IN '(SPADE **HEART DIAMOND** CLUB) COLLECT
   FOR NEW N←1 **TO** 13 **COLLECT**
      <<SUIT,N>>;

would ret DECK ≡
   ((SPADE 1) **(SPADE** 2) ... (SPADE 13) (HEART 1) (HEART 2) ...)

As was stated in (D) above, more than one list or numerical range may
be stepped through in parallel. Below are some examples of parallel
FOR's (*):

```
EXPR PAIR-UP (VECTOR1, VECTOR2);
    FOR NEW X1 IN VECTOR1 FOR NEW X2 IN VECTOR2 COLLECT <X1 CONS X2>;
```

```
'(A B C)        PAIR_UP '(1 3 5 7 9,      =      ((A.1) (B,3) (C,5))
'("JOHN" CDR) PAIRUP '("SMITH" (X))       =      (("JOHN","SMITH") (CDR X))
```

Vector operations also provide an interesting way to accomplish this:

```
'(A B C)        CONS* '(1 3 5 7 9)        =      ((A.1) (B,3) (C,5))
'("JOHN" CDR)  CONS* '("SMITH" (X))       =      (("JOHN","SMITH") (CDR X))
```

```
EXPR STRIP (ITEMS, VECTOR);
    BEGIN NEW V;
        FOR V ON VECTOR FOR NEW I IN ITEMS OO NIL UNTIL I NEQ CAR V;
        RETURN V
    END;
```

```
'(a b x) STRIP '(a b c d e)           =          (c d e)
'(x b c) STRIP '(a b c d e)           =    ,      (a b c d e)
'(a b c d e f) STRIP '(a b c d e)     a          NIL
```

```
EXPR WHERE_IN (X, VECTOR);
    BEGIN NEW V,N;
        FOR V IN VECTOR FOR N+1 TO 1000 DO NIL UNTIL V = X;
        RETURN IF NULL V THEN 0 ELSE N
    END;
```

```
'a WHERE_IN '(b c a d)                =          3
'z WHERE_IN '(b c a d)                =          0
```

(*) I am indebted to Larry Tesler for suggesting these examples.

. SEMANTICS - SECTION 3.10

<WHILE_expression>   ::= WHILE <expression> <DO, COLLECT> <expression>

<UNTIL_expression>   ::= <DO, COLLECT> <expression> UNTIL <expression>

A WHILE expression is the reserved word WHILE, followed by any
expression, followed by either of the reserved words DO or COLLECT
and another expression (the "body" of the WHILE-loop). An UNTIL
expression is either of the reserved words DO or COLLECT, followed by
any expression (the "body" of the UNTIL-loop), followed by the
reserved word UNTIL and another expression.

WHILE and UNTIL expressions are two more of the MLISP
"meta-expressions". They have no direct counterparts in LISP. They
are translated into LISP PROG's. Their execution involves iteration;
it does not involve recursion. Therefore, these loops may be
executed any number of times with no danger of overflowing the
pushdown list.

The execution of WHILE expressions is carried out as follows.
(1) The expression after the WHILE is evaluated. If its value is
    NIL, then the loop exits returning its current value (initially
    NIL).

(2) Then the body of the WHILE-loop is evaluated and a new value for
    the loop is computed. As with FOR expressions, DO and COLLECT
    control how the value of the WHILE-loop is built up. With DO,
    each time the body of the loop is executed, the value that
    results becomes the value of the WHILE-loop; with COLLECT these
    values are APPEND'ed together. Then step (a) is carried out
    again.

UNTIL expressions are very similar to WHILE expressions. The only
difference is that in WHILE-loops the test for the terminating
condition is made first and then the body is executed; whereas in
UNTIL-loops it is made second, after the body has been executed.
This means that in UNTIL-loops, the body of the loop is sure to get
executed at least once; but in WHILE-loops it may not be executed at
all. To get a description of UNTIL-loops, just interchange steps (1)
and (2) above in the description of WHILE-loops.

As an example of the power of using COLLECT with WHILE-loops and
UNTIL-loops, suppose an input file contains a sequence of lists in
the form:

                (DEFPROP <function_name> <lambda_body> <function_type>),

which Is a standard form for LISP 1.6 function definitions. Suppose it Is desired to assemble all the function names In the file Into a list, printing out each function name as it Is read. Each of the following two expressions does this. Concise statements of complex expressions such as this Is one of the primary purposes of MLISP.

L ← WHILE NOT ATOM X←READ() COLLECT <PRINT X[2]>;

X ← READ();   L ← COLLECT <PRINT X[2]> UNTIL ATOM X←READ();

Examples of WHILE expressions:

WHILE A=B DO A←FOO(A,B)

WHILE ATOM X←READ() DO PRINT X

WHILE X≠10 COLLECT PROG2(X ← X+1,<FOO(X,Y)>)

WHILE ¬(X ∈ L) DO X←READ()

WHILE ¬STOP DO
BEGIN
    NEW !X,Y!   SPECIAL !X!
    !X ← READ();
    Y . FOO(!X,READ(),READ());
    IF !X EQ 'STOP THEN STOP←T ELSE PRINT Y
END

Examples of UNTIL expressions:

DO A←FOO(A,B) UNTIL A#B

DO PRINT X UNTIL NOT ATOM X←READ()

COLLECT PROG2(X ← X+1,<FOO(X,Y)>) UNTIL X=10

DO X←READ() UNTIL X ∈ L

DO BEGIN
    NEW !X,Y!   SPECIAL !X!
    !X ← READ();
    Y ← FOO(!X,READ(),READ());
    IF !X EQ 'STOP THEN STOP←T ELSE PRINT Y
END
UNTIL STOP

. SEMANTICS - SECTION 3.11

```
<assignment_expression>  ::=   <regular_assignment>
                          |     <array_assignment>
                          |     <index_assignment>
                          |     <decomposition>

<regular_assignment>     ::=   <identifier> ← <expression>

<array_assignment>       ::=   <identifier> (<argument_list>) ← <expression>

<index_assignment>       ::=   <identifier> [<argument_list>] ← <expression>

<decomposition>          ::=   <simple_expression> ←← <expression>
```

The assignment expression is one of the most powerful expressions in
MLISP. With it, one can change the value of a variable, store into
an array, change a single element in a list leaving the other
elements untouched, or decompose a list according to a "template".
In all cases, the value of an assignment expression is the value of
the expression on the right-hand side.

Making an assignment expression a <simple_expression> has an
interesting property: it removes the assignment operator (←) from the
normal realm of infix operators. In particular, when

        ATOM X ← READ()

is encountered, it is reduced as follows:

        ATOM   X   ←   READ()
                 ↓
<prefix_operator> <identifier> ← <expression>
                 ↓
<prefix_operator> <assignment_expression>
                 ↓
<prefix_operator> <simple_expression>
                 ↓
<simple_expression>
                 ↓
<expression>

and so the prefix will modify the entire assignment expression.
However, for infix operators, when

        ATOM X & READ()

is encountered, it is reduced as:

     ATOM   **X**   **&**   **READ( )**
       ↓

<prefix_operator> <identifier>   <infix_operator> <expression>
       ↓

<prefix_operator> <simple_expression> <infix_operator> <expression>
       ↓

<simple_expression>   <infix_operator> <expression>
       ↓

<expression>

and so the prefix will modify only the identifier. The assignment operator acts like it has an extremely high loft binding power (binding powers are discussed In SECTION 3.3), and an extremely low right binding power, which It does; the left binding dower is 1001 and the right is 0. In other words, the left binding power of ← is stronger than any inflxorprefix, while the right binding power of ← is weaker than any inflx or prefix. Therefore,

           ATOM X ← READ( )   →   (A T O M (SETQ X (READ)))
whereas
           ATOM X & READ( )   →   (AND (ATOM X) (READ))
           ATOM X CONS READ( )   →   (CONS (A T O M X)(READ))

Regular assignment

The regular assignment is the al-molest of the options. It Just translates Into SETQ. The left-hand side must be an Identifier; the right-hand side may be any expression. Example:

        X ← Y + 1   →   (SETQ X (ADD1 Y))

Array assignment

The array ● aslgnment is the means for storing values Into array cells. LISP 1,6 permit8 1-5 dimensional arrays a8 a data structure. The assignment operator I8 here translated Into STORE. The left-hand side must be a call on an array; the right-hand side may be any expression. Example:

        A(I,J) ← Y + 1   →   (STORE (A I J) (ADD1 Y))

Index assignment

The Index assignment provides a means for changing a single element In a list, leaving the other elements untouched. This facility Is not readily available In LISP. The left-hand side must be an Identifier whose value Is a list, followed by an Index list as In Index expressions (SECTION 3,131; the right-hand side may be any expression. The Index list Is used to reference the location In the list which Is to be changed. Into this location Is placed the value of the right-hand side. Example: If

        L = (A   B (C D) E F),
then
        . L[3,1] ← 1

would change the value of L to

        L = (A B (1 D) E F),

It Is permissible to place values Into cells which did not exist In the original list; In this case, NIL Is placed Into any locations that had to be created. Example:

        L[3,5] ← 1

would change the value of L to

        L = (A B (C D NIL NIL 1) E F),

Decomposition assignment

The decomposition assignment is the most powerful in MLISP. It provides a means of decomposing a list according to a "template". The left-hand side is a simple expression which 9hould evaluate to an s-expression (the template); the right-hand side may bg any expression. The template is an s-expression composed of variables, each of which is to be set to the element in the corresponding location of the right-hand side, hereafter called the "RHS".

One ward of caution: If the decomposition assignment expression is used in a compiled program, all the variables in the template must be declared **SPECIAL.** Otherwise, the variables will not bs aet correctly.

Example:

> '(X Y Z) ←● '(A B (C D) E F)

would set

> X to A
> Y to B
> Z to (C D).

Regular assignment expressions are a subset of decomposition assignment expressions. Any regular assignment, such as:

> ・   X ← Y + 1

may be written as a trivial decomposition assignment:

> 'X ←● Y + 1

provided X is declared SPECIAL.

The deoompogltlon assignment expression ralggg the interesting possibility that some variables may fall to get set because the template structure in which they occur dogs not correspond to the structure of the right-hand side (RHS). Any suoh variable which cannot be set to an RHS value I9 set to NIL. A template variable will always be set to an RHS value if thg template position in which it oocurg is "compatible" with the corresponding RHS position. The only "incompatible" case is when the template position is a

non-atomic s-expression, and the corresponding RHS position is an atom. In this case, all variables occupying the incompatible template position will be set to NIL,.. Example:

    '((X Y) Z) ←• '(A B (C D) E F)

would set

    X,Y to **N I L**   Because the first template position is a
                    list, (X Y), whereas the firstRHS position
                    Is an atom, A. Thus the first template
                    position is "incompatible" with the firstRHS
                    position, and the variables In it are set
                    to NIL.
    Z to B   Because the second template position Is
                    "compatible" with the secondRHS position.

The CDR of the **RHS** may be obtained by a dotted pair In the template:

    '(X Y . Z) ←• '(A B (C D) E F)

would set

    X to A
    Y to B
    Z to ((C D) E F).

Suppose L = (A B (C D) E F). The listL Itself could be used as the template:

    L ←• '(1 2 (3 4 5 6 7)(8 9))

would set

    A to 1   In thiscase A, B, C,D,E and F **must** all b e
    B to 2   declared SPECIAL.
    C to 3
    D to 4
    E to (8 9)
    F to NIL,

Finally, a "match anything" symbol is available for use in the template: an underbar (_), This symbol will match any amount of list structure necessary to make the template match the RHS, Example:

  '(_ X) ← '(A B (C D) E F)

would set

        X to F   Because the template specifies that the value
                              for the variable X should occur as the last
                              ● lanßnt In the RHS, The underbar matches
                              (A B (C D) E) In this case,

Using the underbar symbol in a template causes the evaluation of the decomposition assignment expression to proceed differently: previously, any variable would be set It It was In a template position compatible with the corresponding RHS position, Using underbars, however, may require that the template structure match EXACTLY the RHS structure, Consider the example above in which X and Y failed to get set, We could now write:

  '(_ (X Y) Z _) ← '(A B (C D) E F)

which would set

        X to C
        Y to D
        Z to E,

Note: neither '(_ (X Y) Z) nor '((X Y) Z _) would work, because in the first case the RHS would have to be in the form(.,.(**)*), which it isn't; and In the second case It would have to be In the form ((* *) * ,,,), which It also Isn't,

The user should experiment with the decomposition assignment to make sure -ho understands Its operation,

Examples of assignment expressions:

Regular assignments:

```
X ← A + 10                      →      (SETQ X (PLUS A 10))
x ← Y ← Z ← NIL                 →      (SETQ X (SETQ Y (SETQ Z NIL)))
X . A ← B ← 10                  →      (SETQ X (PLUS A (SETQ B 10)))
x ← A * B ← C ← D               →      (SETQ X (TIMES A (SETQ B (PLUS C D))))
NOT ATOM X ← READ()             →      (NOT (ATOM (SETQ X (READ))))
NOT ATOM X & READ()             →      (AND (NOT (ATOM X)) (READ))
NULL A ← B . FOO(X)             →      (NULL (SETQ A (SETQ B (FOO X))))
NULL A | B | FOO(X)             →      (OR (NULL A) B (FOO X))
NULLCA | B | FOO(X))            →      (NULL (OR A B (FOO X)))
A ← BEGIN
       NEW TEMP;                →      (SETQ A (PROG(TEMP)
       TEMP . READ();                      (SETQ TEMP (READ))
       PRINT 'START;                        (PRINT (QUOTE START),
       RETURN TEMP                          (RETURN TEMP)))
    END
```

Array assignments:

```
X(1) ← A + 10                   →      (STORE (X 1) (PLUS A 10))
A(I,J) ← FOO(X)                 →      (STORE (A I J) (FOO X))
⌀□ . A(1) ← NIL                →      (STORE (A 0) (STORE (A 1)  NIL))
X(1) ← A ← B(0) . 10            →      (STORE (X 1) (PLUS A (STORE (B 0) 10)))
A(I,FOO(J),K+1) ← T             →      (STORE (A I (FOO J) (ADD1 K)) T)
A(1,2,3,4,5) ← 'FIVE_D          →      (STORE (A 1 2 3 4 5) (QUOTE FIVE_D))
NOT ATOM X(1) ← READ()          →      (NOT (ATOM (STORE (X 1) (READ))))
NOT ATOM X(1) & READ() .        →      (AND (NOT (ATOM (X 1))) (READ))
NULL A(1) ← B ← FOO(X)          →      (NULL (STORE (A 1) (SETQ B (FOO X))))
NULL A(1) I B | FOO(X)          →      (OR (NULL (A 1)) B (FOO X))
NULL(A(1) I B | FOO(X))         →      (NULL (OR (A 1) B (FOO X)))
```

Index assignments:

Suppose L = (A B (C D) E F),

```
L[1] ← 1          would sot     L = (1 B (C D) E F)
L[2] ← 1          would set     L = (A 1 (C D) E F)
L[3] . 1          would set     L = (A B 1 E F)
L[3,1] ← 1        would set     L = (A B (1 D) E  F)
L[8] ← 1          would sot     L = (A B (C D) E F NIL NIL 1)
L[2,3,2] ← 1      would set     L = (A (NIL NIL (NIL 1)) (C D) E F)
```

Decomposition assignments:

Suppose L = (A B (C D) E F).

```
L ← '(1 2 3)                              would set
                                          A = 1
                                          B = 2
                                          C = D = E = F = NIL

L ← '(1 2 (3) 4)                          A = 1
                                          B = 2
                                          C = 3
                                          D = E = 4
                                          F = NIL

L ← '(1 2 (3 4) 5 6)                      A = 1
                                          B = 2
                                          C = 3
                                          D = 4
                                          E = 5
                                          F = 6
```

```
'(_ X Y Z)      ← '(A B (C D) E F)        X = A
'(X _ Y Z)      ← '(A B (C D) E F)        Y = B
'(X Y Z _)      ← '(A B (C D) E F)        Z = (C D)

'(_ X Y Z)      ← '(A B (C D) E F)        X = B
                                          Y = (C D)
                                          Z = E

'(X _ Y Z)      ← '(A B (C D) E F)        X = A
                                          Y = (C D)
                                          Z = E

'((_ X) Y Z)    ← '(A B (C D) E F)        X = C
                                          Y = E
                                          Z = F

'(: _)          ← '(A B (C D) E F)        X = F

'((_ X) _)      ← '(A B (C D) E F)        X = D

'((_ X) _)      ← '(A B (C D) E F)        X = A

'(X _ Y)        ← '(A B (C D) E F)        X = A
                                          Y = F
```

Again, I wish to emphasize that if a decomposition assignment expression is used in a compiled program, all the variables in the template (the left-hand side) must be declared SPECIAL.

, SEMANTICS - **SECTION** 3.12

```
<function_call>    ::=   <identifier>              ( <argument_list> )
                    |     <LAMBDA_expression> ı ( <argument_list> )

<argument_list>    ::=   <expression> (, <expression>)*
                    |     <empty>
```

A functioncall is an identifier (a function name) or a LAMBDA expression (a function body) **followed** by an argument list enclosed in parentheses. An argument list is any **number** of expressions, possibly none, separated by commas.

Little **need** be saidabout this. Essentiallytheonly difference between this and the **LISP** way of writing function calls is that the function name has been **brought** outside the parentheses. Also the arguments are separated by commas. The arguments **may** be any arbitrary expressions.

Examples of function calls:

```
FOO(X)                    →        (FOO X)
FOO(X,Y,Z)                →        (FOO X Y Z)
FOO()                     →        (FOO)
FOO(A+B, C)               →        (FOO (PLUS A B) C)
FOO(IF A THEN B ELSE C).            (FOO (COND (A B) (T C)))
```

Thésame function calls, writtenas **LAMBDA** expressions:

```
LAMBDA(L)) FOO(L); (X) →           ((LAMBDA (L) (FOO L)) X)

LAMBDA- (A,B,C);
  FOO(A,B,C);             →        ((LAMBDA (A B C)(FOO A B C)) X Y Z)
(X,Y,Z)

LAMBDA() FOO(); ()        →        ((LAMBDA NIL (FOO)))

LAMBDA (X,Y,Z);
  FOO(X+Y, Z);            →        ((LAMBDA (X Y Z) (FOO (PLUS X Y) Z)) A B Cl
(A,B,C)

LAMBDA      (L); FOO(L); →          ((LAMBDA (L) (FOO L)) (COND (A B) (T C)))
(IF A THEN B ELSE C)
```

, SEMANTICS - SECTION 3.13

<index_expression> ::= <simple_expression> [<argument_list>]

<argument_list>   ::= <expression> (, <expression>)*
                   | <empty>

An Index expression is a simple expression, followed by an argument list enclosed In square brackets []. An argument list is any number of expressions (possibly none) separated by commas,

The MLISP Index expression fills a critical deficiency in LISP: there is no easy way to reference an arbitrary cell in a list, CAR will obtain the first element, CADR the second, CADDADDDDR the third element in the fifth element of the list, etc, But CADDADDDDR is neither (1) very understandable, not (2) variable, The latter is Important since It occasionally happens that the user does not know until run-time which element of a list ho will wish to access,

The MLISP Index expression eliminates these objections, L[5,3] is the same as CADDADDDDR, but it is a good deal more readable, Furthermore, the Index arguments may contain variables, In fact expressions: L[N], L[I,J,K], L[2*N], etc, The Index expression, then, is a generalized version of CAR, (A generalized version of CDR also exists (SUFLIST) and is explained in SECTION 5.2,)

When Index expressions are compiled, they are expanded by macros into highly optimized code:
        L[5,3]   (CADDAR (CDDDDR L))
This insures that the execution of Index expressions will be very efficient in compiled programs, In interpreted programs, it is more efficient to issue a call on a run-time function,

Examples of Index expressions:

Suppose L = (A B (C (D E) F) G H).

L[1]	= A	→	(CAR L)
L[2]	= B	→	(CADR L)
L[3]	= (C (D E) F)	→	(CADDR L)
L[3,1]	= c	4	(CAADDR L)
L[3,2,1]	= D	→	(CAAR (CDADDR L))
'(A B C)[3]	= c	→	(CADDR (QUOTE (A B C)))
GET(X,'VALUE)[2]		→	(CADR (GET X (QUOTE VALUE)))
(L1 ● L2)[1,2]		→	(CADAR (APPEND L1 L2))
(FOR NEW I IN L COLLECT <CAR I>)[2*N, M/3 + 1]			

. SEMANTICS - SECTION 3.14

```
<list_expression>  ::=  <  <argument_list>  >

<argument_list>    ::=  <expression> (, <expression>)*
                   |    <empty)
```

A list expression is a left angled **bracket** (<), **followed** by an argument list, followed by a right **angled** **bracket** (>). An argument list is any number o f expressions, possibly none, separated by commas.

This is the MLISP equivalent of the LISP LIST function: <A,B,C> Is translated Into (LIST A BC),<A,B,<C,D>,E,F> Into (LIST A B (LIST C D) E F), etc. Angled brackets are used to make lists concise and to cut down further' on the number of parentheses needed. As with function calls, the arguments inside the list brackets may be any arbitrary expressions.

Examples o f list expressions:

```
<>                          •    (LIST)
                            →    (LIST A)
<A,B,C>                     →    (LIST A  B  C)
<A,<B>,C>                   →    (LIST  A (LIST B) C)
<'A,B CONS C CONS D>        •    (LIST (QUOTE A)(CONS B (CONS  C  D)))
<X+10, <<Y>>, NIL>          →    (LIST (PLUS X 10) (LIST (LIST Y)) NIL)
<IF A THEN <B>  ELSE  C> →       (LIST (COND  (A (LIST B))(T C)))
```

. SEMANTICS - SECTION 3.15

```
<quoted_expression>    ::=   ' <s-expression>

<s-expression>         ::=   <atom>
                       |     ( )
                       |     ( <s-expression> . <s-expression> )
                       |     ( <s-expression> ((,) <s-expression>}* )
```

A quoted expression is the quote mark (') followed by an
s-expression. An MLISP s-expression IS just the same as a LISP
s-expression, except that each identifier in it must be a legal MLISP
identifier. In particular, any special characters (characters which
are not MLISP letters or digits) must have the literally character
(?) in front of them.

Note that there is one fewer level of parentheses needed with the
MLISP quoted ● xprarsion than with the LISP QUOTE function. This is
part of the effort to cut down on the number of parentheses required.

Examples of quoted expressions:

```
'A                          →    (QUOTE A)
'NIL                        →    (QUOTE NIL)
' 0                         →    (QUOTE NIL)
'(A  B  C)                  →    (QUOTE (A B C))
'(A,B,C)                    →    (QUOTE (A B C))
'(a b c)                    →    (QUOTE (a b c))
'(A,B)                      →    (QUOTE (A,B))
'(A  B ?*C?* 0 E)           →    (QUOTE (A B *C* 0 E))
'(A, 16.0, (E,F), 0)        →    (QUOTE (A 16.0 (E,F) 0))
'(A    (B,C) ?= D , E)      →    (QUOTE (A (B,C) = D , E))
```

. **SEMANTICS** • SECTION 3.16

```
<identifier>              ::=  <letter> ( ⊂<letter>, <digit>⊃ )*

<letter>                  ::=  ⊂A, B,  C,..., Z, a, b, c,..., z, _, :, !⊃
                           |   <literally_character> <any_character except %>

<literally_character>     ::=  ?
```

An identifier is an MLISP letter followed by any number of MLISP letters or digits. An MLISP letter is any of the upper or lower case letters of the alphabet, or an underbar (_), colon (:) or exclamation point (!), or any character except % preceeded by the literally character. The literally character is a question mark (?). The comment character (%) may not be included because LISP 1.6 won't allow it to be *used* as anything except the start or end of a comment.

Underbar, colon and exclamation point are considered to be letters so that the user can easily create unusual names for variables. The literally character is a flag to the translator to take the next character literally and consider it to be a letter, even if the next character would ordinarily have a different meaning to MLISP. This enables the user to include virtually any character except % in variable names. However, the user must be sure that his LISP system won't object t o any o f the characters in his identifiers. Note: all of the functions and variablenames used by the MLISP translator begin with an ampersand (&), so it is unwise to use such names.

Examples of identifiers:

```
X                                 →    X
X1                                •    X1
AVERYLONGSTRINGOFLETTERS          →    AVERYLONGSTRINGOFLETTERS
A_VERY_LONG_STRING_OF_LETTERS     →    A_VERY_LONG_STRING_OF_LETTERS
x                                 →    x
x1                                →    Xl
averylongstringofletters          →    averylongstringofletters
a_very_long_string_of_letters     →    a_very_long_string_of_letters
UPPER_and_lower_case_IDENTIFIER   →    UPPER_and_lower_case_IDENTIFIER

DSK!                              →    DSK!
TTY!                              →    TTY!
!SYSTEM_VARIABLE_357a             →    !SYSTEM_VARIABLE_357a
33                                4    ?
?)                                •    )
?1                                →    1    (an identifier, not a number)
AB?*C?*DE                         →    AB*C*DE
?*!:_?#?@?$?≠?(?)?[?]?<?>          →    *!:_#@$≠()[]<>
```

. **SEMANTICS** - SECTION 3.17

```
<number>          ::=   <integer>
                  |     OCTAL <octal_integer>
                  |     <real>

<integer>         ::=   <digit> (<digit>)*

<digit>           ::=   =0,1,2,3,4,  3,   6,   7,   8,   9=

<octal_integer>   ::=   <octal_digit> (<octal_digit>)*

<octal_digit>     ::=   =0,1,2,  3,  4,  3,   6,  7=

<real>            ::=   <integer> <exponent>
                  |     <integer> , <integer> (<exponent>)

<exponent>        ::=   E (=+,  -=) <integer>
```

Three types of numbers are permitted In MLISP: Integers (base 10), Integers preceeded by the reserved word OCTAL (base 8), and real numbers (base 10 again). An Integer It anysequence of digits. A real number Is either an Integer followed by an exponent or two Integers separated by a decimal point, optionally followed by an exponent. An exponent Is the letter E, optionally followed by 4plus or minus sign, followed by an Integer. There should never be spaces between any of the parts of 4number, except after the word OCTAL.

All number8 are taken to be decimal numbers unless preceeded by the word OCTAL. Octal numbers are Included because they are used In many computer applloatlons. Exponents provide 4 compact way of representing very large or very small real numbers. Only Integer exponents are allowed, but they may be either positive or negative.

Plus (+) and minus (-) signsare not part of tho syntax tar numbers (except In the exponent). Plus and minus signs are delimiters, and they are treated as either prefix or Inflx operators by the translator.

Examples of numbers:

1	→	1
10	→	10
145968	→	145₉68
987,005	→	9.87005E2
13E+4	→	1.3E5
0.1	→	1.0E-1
0.000123E-5	→	1.23E-9
OCTAL 10	→	8 (decimal)
OCTAL 144	→	100 (decimal)
OCTAL 777777	→	262143 (decimal)
-145.12	→	(MINUS 1.4512E2)
X-145.12	→	(DIFFERENCE X 1.4512E2)
+98765.43210	→	9.87654321E4
x+98765.43210	→	(PLUS X 9.87654321E4)

Note: .1   is not allowed:use 0.1 instead.

, SEMANTICS - SECTION 3.18

<string> ::= "(<any_character except " or X>)* "

A string Is a string quote ("), followed by any sequence of characters except the string quote or X, followed by 4 second string quote,

Strings are a special MLISP data structure Introduced primarily to facilitate Input/output, Several string manipulation features are included In MLISP to make string handling easy, These are described in SECTION 5.1, However, MLISP Is not a string-manipulation language! It is a list-processing and symbol-manipulation language. Most of the string-handling routines are fairly time consuming, requiring an execution time proportional to the length of the string(s) Involved'; Therefore, If possible limit string manipulation to Input/output operations, or at least to operations which are not performed often, If It Is necessary to do a lot of string manipulating, the user should consider using some other, more suitable, language, since MLISP processes strings inefficiently,

String are stored by LISP 1.6 as un-INTERNED (I.e. not on the OBLIST) atoms having a print name consisting of the characters In the string, and Including both string quotes,

Examples of strings:

""	→	(QUOTE "")
"THIS IS A STRING"	→	(QUOTE "THIS IS A STRING")
"This Is also a string."→		(QUOTE "This la also a string,")
"123,:#<>()?;←"	•	(QUOTE "123,:#<>()?;←")
" "	→	(QUOTE " ")

. USER OPERATION OF MLISP - SECTION 4.1

This section tells the user how to get a n MLISP program running.

(A) Translating MLISP Programs

There are two versions of MLISP, both residing on the system area   of
the disk:

          MLISP   - a core Image containg LISP and MLISP,

          MLISPC - a core Image containing LISP, MLISP, PPRINT (the
                    "pretty-print" functions), 'and the LISP compiler,

These core Images may be loaded by typing:

          R MLISP   or   R MLISP <core_size>
and
          R MLISPC   or   R MLISPC <core_size>

The core size of MLISP is 25K, and Of MLISPC 35K,   These   should   be
sufficient to handle all but the largest programs,   If not, a larger
core size will have to be specified,

The MLISP core Image should be used If the user wants to translate
his MLISP program and then execute It,   The MLISPC version should be
used   only   If the user want8 to translate his MLISP program and then
compile It or pretty-print   out   Its LISP translation,   For   large
(debugged) programs,   the most ● fflclent use of core Is achieved by
compiling the MLISP program with MLISPC,   and   then reading the
compiled code Into a "fresh" LISP system (I,e, containing nothing
else but LISP), Compiling the program has the following advantages:
(1) The program runs about 10 times faster compiled than Interpreted.

(2) MLISPC Incorporates some elaborate macros which expand FOR-loops,
     WHILE-loops, UNTIL-loops and Index expressions Into   highly
     optimized code,   This further speeds up their execution,   MLISP
     Is very compiler oriented; by far the most efficient execution of
     MLISP meta-expressions Is by compiled code,

(3) Compiled   code   requires less space than the corresponding
     list-structure Interpreted code,

(4) Function definitions don't have   to be marked by the garbage
     collector   every time a garbage collection occurs (a significant
     time savings for large programs),

To avoidconfusion, two facts should be kept In mind when using
MLISP!

(a) In WRITING your program, you will be communicating with MLISP.
All expressions in the program must be legal MLISP expressions.

(b) In RUNNING your program, you will be communicating with LISP.
All expressions to be executed, read or printed must be legal
LISP • xpre88lons,

After the user ha8 loaded acoreimage by typingoneof the two
commands above, he may beginstranslating his MLISP program by calling
the top level function named, you guessed it, "MLISP". "MLISP" Is an
FEXPR which takes from 1 to 4 arguments. These arguments will be
explained by examples. The full command is!

    (MLISP (<device>) <file_name> (=T, NIL, NIL NIL=))

where () and => mean "optional" and "alternatives" respectively. A
<device> is either a physicaldevice like a disk or dec tape (e.g.
DSK! or DTA1!)oraproject-programmer pair representing a disk area
(e.g. (1,DAV) represents [1,DAV]).

Examples of the too level function "MLISP":

.R MLISP   would translate and execute a program
*(MLISP FOO)   on the disk file **FOO**

.R **MLISP**   would do exactly the same thing
*(MLISP DSK: FOO)

.R **MLISP**   would translate and execute a program
*(MLISP (1,DAV) FOO)   on DSK:FOO[1,DAV]

.R MLISPC   would translate a program on DSK:FOO
*(MLISP **FOO** T)   and compile It onto DSK:FOO.LAP

.R **MLISPC**   would translate a program on DSK:FOO
*(MLISP FOO NIL)   and pretty-print the LISP translation
                                         onto DSK:FOO.LSP

.R **MLISPC**   would do the same thing, except that
*(MLISP **FOO** NIL NIL)   the expansi on of all LISP and **MLISP**
                                         macros is suppressed,   Ordinarily,
                                         all macros (FOR-loop macros, **PLUS**,
                                         etc.) are expanded before printing,
                                         which enables tha user to see exactly
                                         what coda will be executed,

.R **MLISPC**   would do exactly the same thing
*(MLISP DSK: FOO **NIL** **NIL**)

.R **MLISP**   would translate and execute a program
*(MLISP (FOO,BA$_Z$))   on DSK:FOO,BA$_Z$

.R MLISP   would translate and execute a program
* ☎♦●♦✗❼ DTA1:(FOO,BA$_Z$))   on DTA1:FOO,BA$_Z$

.R **MLISPC**   would translate   a   program   on
*(MLISP MTA0: (FOO,BA$_Z$) T)   MTA0:FOO.BA$_Z$ **and** compile It onto
                                         DSK:FOO,LAP

(B) Translating Under Program Control

It is sometimes desireable to call the MLISP translator under program control. This is made possible " by the special MLISP function "MTRANS", a function of no arguments. Calling MTRANS ha8 the following effects:

(1) An MLISP <expression> Is road from the currently selected Input device. The first character read should be thefirst character In the expression. An MLISP <expression> differsfrom an MLISP <program> only in that the last character need not be a period; It may be any suitable expression-stopping character, usually a semicolon (;).

(2) The LISP translation Is returned as the value of MTRANS.

The funotion "MLISP" should not be oal led f r o m within a program, since It hasseveral side ● ffeotr, whloh are generally undesireable In a program; for example, the funotlon RESTART Is redefined. MTRANS has no side effects.

Note: It MTRANS Is called, the entire MLISP translator must b a ● vellabla. This means that programs using MTRANS should only be run Interpreted.

(C) Loading Compiled Programs

There is a file called **UTILS** on the system area of the disk containing run-time functions. This file must be loaded if the user has either compiled his MLISP program onto a .LAP file or pretty-printed it onto a .LSP file. **UTILS** is already loaded into both the **MLISP** and **MLISPC** core images, so that if the user simply wants to translate and run his MLISP program, the run-time functions will be available.

To read in an **MLISP** program after it has been compiled by MLISPC, set up a **LISP** system with sufficient Binary Program Space to hold the compiled code, and then type:

        (INC (INPUT DSK: (<file_name>.LAP) SYS: UTILS))

The file **UTILS** should always be read in last since one of the things it does is set IBASE and BASE (the input and output radicles for numbers) to 10 (i.e. decimal). Thereafter, all numbers read or written will be interpreted as decimal numbers. The user should be careful to set IBASE to 8 (i.e. octal) if he wants to read in more LAP code, since LAP expects its numbers to be in octal form, and then reset IBASE to 10 afterwards.

the following sequence would translate and compile an MLISP program on the disk file FOO, and then read in the compiled code:

```
.R MLISPC
*(MLISP FOO T)

... <MLISP and compiler typeout> ...

***END-OF-RUN***
*↑C

.R LISP <coresize>

ALLOC?   ... <allocation> ...

*(INC (INPUT DSK: (FOO.LAP) SYS: UTILS))

... <LAP typeout> ...

*
```

, USER OPERATION OF MLISP - SECTION 4.2

This section is only for those hardy souls attempting to reconstruct MLISP on a LISP 1.6 system. Below is the sequence of commands necessary to reassemble both the MLISP and the MLISPC core images. In SECTION 4.3 is listed the contents of the various MLISP source files.

To Reconstruct MLISP:

```
,R LISP 24

ALLOC? Y
FULL WDS=2000
BIN,PROG.SP=8000
SPEC,PDL=_
REG, PDL=_
HASH=_

AUXILIARY FILES?Y
SMILE?_
ALVINE?_
TRACE?,
LAP?Y
DECIMAL?_

*(INC (INPUT DSK:
   (MLISP,LAP)
   (RUNFN1,LAP)
   (RUNFN2,LAP)
   MINIT
   SETQS))

...,<type out>...

*(SCANNER1INIT)
**SCANS

LOADER 1K CORE

*(SCANNER2INIT)
NIL

**↑C

,SAVE QSK MLISP
```

To Reconstruct MLISPC:

```
,RLISP  34

ALLOC? Y
FULL WDS=3000
BIN,PROG.SP=23000
SPEC,PDL=_
REG, PDL=_
HASH=_

AUXILIARY FILES?Y
SMILE?_
ALVINE?_
TRACE?,
LAP?Y
DECIMAL?_

*(INC (INPUT DSK:
   (MLISP,LAP)
   (MACROS,LSP)
   (MACRO1,LAP)
   (RUNFN2,LAP)
   (PPRINT,LAP)
   (COMPLR,LAP)
   MINIT
   SETQS))

...,<type out>...

*(SCANNER1INIT)
**SCANS

LOADER 1K CORE

*(SCANNER2INIT)
NIL

**↑C

,SAVE OSK MLISPC
```

The correct oore Images will now be saved under "MLISP" and "MLISPC".
A little explanation about these two sequences Is necessary. The
underbar (_) In the first few lines represents a space; this merely
Instructs LISP to use the standard allocation. The line reading:

         (INC (INPUT DSK: (MLISP,LAP) ...)

assumes that all of the LAP files listed have been compiled by the
LISP compiler. The file **COMPLR** should be the LISP compiler Itself.

The line ****SCAN%** (S stands for ALTMODE) loads the MLISP scanner
package, which must have been compiled by **MACRO** and be In .REL
format,

If the machine language scanner Is not to be used, then the LISP
scanner listed In SECTION 7,3 should be compiled by the LISP compiler
and read In with the other LAP files. Note: all LAP files must be
read before the file SETQS, because SETQS changes IBASE, the Input
radix for numbers, from 8 (octal) to 10 (decimal). LAP expects IBASE
to be 8.

If the LISP scanner Is used, the following lines should be omitted:

*(SCANNER1INIT)
**SCANS

LOADER 1K CORE

*(SCANNER2INIT)
NIL

, USER OPERATION OF MLISP - SECTION 4.3

This is a reference file of the MLISP source files,

FIlE	Contents
MLISP	The MLISP translator functions -- **In LISP**
MINIT	Initialization for the **MLISP** translator (reserved words, abbreviations, precedences, etc,) -- in **LISP**
SETQS	Initialization of the MLISP globally-defined atoms -- in LISP

SCAN.MAC	The machine language scanner for **MLISP** -- in DEC **MACRO**

, RUN-TIME FUNCTIONS - SECTION 5.1

This section describes the string-handling functions of MLISP. Other
run-time functions available to the user are described in the next
section. Strings are described In SECTION 3.18; they ● xlst primarily
to facilitate input/output.   To make string handling easy, MLISP
Includes the following set of primitives.

STR (sexp) - "STRINGIFY"
     This takes one argument, which may be any s-expression, and
     returns a string containing the charactors In that s-expression
     (Including spaces and parentheses)'

STRP (sexp) - "STRING PREDICATE"
     This takes one argument, which mry be any s-expression.   Returns
     TRUE if the s-expression Is a string, NIL otherwise.

STRLEN (string) - "STRING LENGTH'
     This takes one ● rqumentc a string, and returns an Integer equal
     to the number of characters In the string (not counting the
     string quotes),

A T (string)- "ATOMIZE"
     This takes one argument, a string, and returns an atom having a
     printname made up of the character8 In the string (not Including
     the string quotes),

CAT (string1, string2) - "CONCATENATE"
     This takes two arguments and returns a string made up of their
     conoatenation,   The arguments need not be strings, If either
     argument Is not a string, It Is first converted to one, and then
     the conoatenation Is carried out,   CAT, being a function of two
     arguments, may be used as an Infix!
        string1 CAT string2.

SEQ (string1, string2) -   "STRING EQUAL"
     This takes two arguments, both strings, and returns T If they are
     Identical, NIL otherwise. The LISP function EQ cannot be used
     because strings are atoms which are not on the OBLIST,   As with
     CAT, SEQ may be used as an Infix!
            string1 SEQ string2.

SUBSTR (string, start, length) - "SUBSTRING"
     This takes three arguments, the first being a string and the
     other two being Integers. It returns a substring of the first

argument beginning with the character in position "start"
(counting from 1) and continuing for "length" characters.
"length" need not be a number, if it is not, then the rest of the
string is taken.

PRINTSTR (string) - "PRINT STRING"
    This takes one argument, a string, and prints it on the current
    output device without the string quotes, followed by a carriage
    return. The value of **PRINTSTR** is the value of its argument (the
    same as with PRINT).

Examples of the string-handling functions:

STR 'STRING	=	"STRING"
STR "STRING"	=	"STRING"
STR '(A (B,C) D)	=	"(A (B , C) D)"
STRP "THIS IS A STRING,"	=	T
STRP '(THIS IS NOT ONE)	=	NIL
STRP ""	=	T
STRLEN "THIS IS A STRING,"	=	17
STRLEN **STR 'STRING**	•	6
STRLEN ""	=	0
AT "STRING"	=	STRING
AT "THIS IS A STRING,"	=	THIS/IS/A/ STRING/,
AT ""	=	Illegal
STR AT "THIS IS A STRING,"	=	"THIS IS A STRING,"
AT STR 'THIS? IS? A? STRING?,	=	THIS/ IS/ A/ STRING/,
"THIS IS A " CAT "STRING,"	=	**"THIS IS A STRING,"**
"THIS IS A " CAT 'STRING?,	=	**"THIS IS A STRING,"**
"A PERIOD " CAT "(.)"	=	**"A PERIOD (.)"**
"A PERIOD " CAT '(?.)	=	**"A PERIOD (.)"**
"A PERIOD " CAT <PERIOD>	=	**"A PERIOD (.)"**
"STRING" SEQ "STRING"	=	T
"STRING" SEQ STR 'STRING	=	T
"STRING" SEQ "STRING,"	=	NIL
SUBSTR("THIS IS A STRING,",6,4)	=	"IS A"
SUBSTR("THIS IS A STRING,",100,5)	=	" "
SUBSTR("THIS IS A STRING,",5,100)	=	" IS A STRING,"
SUBSTR("THIS IS A STRING,",5,'REST)	3	" IS A STRING,"

PRINTSTR "A STRING,"	prints	A STRING,	value =	"A STRING,"
PRINT "A STRING,"	prints	**"A STRING,"**	value =	"A STRING,"

. RUN-TIME FUNCTIONS • SECTION 5.2

This section describes some general-purpose routines that have been judged sufficiently useful to be Included In the set of run-time functions available to the MLISP user. All of these functions are short and have been compiled, so that they require very little binary program space and almost no free storage. The functions NEQ, NEQUAL, LEQUAL and GEQUAL are expanded by macros when the MLISP program In which they occur Is compiled. This makes using these functions In a compiled program very efficient.

PRELIST (list, integer) • **"PREFIX OF LIST"**
   This takes two arguments, a list and an Integer, **PRELIST** returns a list of the first "Integer" elements of Its first argument. If: there are fewer than "Integer" elements In It, PRELIST **returns as** many as It can (I.e. the whole list).

   PRELIST may be abbreviated ↑ (up arrow):   PRELIST(L,6) $\equiv$ L↑6

SUFLIST (list, integer) • **"SUFFIX OF LIST"**
   This takes the same two arguments as PRELIST: a list and an Integer. SUFLIST **returns** a list formed by taking "Integer" CDR's of Its first argument. If It exhausts Its first argument before It runs out of CDR's, It stops at NIL (I.e. It will return NIL).

   SUFLIST Is the "compliment" of **PRELIST** In the sense that:

        PRELIST(L,N) ⊕ SUFLIST(L,N) =   **L**

   for all lists L and for all Integers N. **SUFLIST** Is a generalization of CDR:

        COR L $\equiv$ SUFLIST(L,1)
        COOR L $\equiv$ SUFLIST(L,2)
        CODR   CDDDDR L $\equiv$ SUFLIST(L,6)

   SUFLIST Is more powerful than CDR because the second argument may be a variable (If fact, any expression), thereby permitting the user to defer until run-t/me his decision on how many CDR's to take.

   SUFLIST may be abbreviated ↓ (down arrow);   SUFLIST(L,6) $\equiv$ L↓6

NEQ (sexp1, sexp2) -   "NOT EQ"
    This takes two arguments, which may be rny s-expressions, and
    returns TRUE if they are not EQ to each other, NIL otherwise.
    The LISP translation Of X NEQ Y:
        (NEQ X Y)
    Is expanded by macros to:
        (NOT (EQ X Y))
    If It is compiled,

NEQUAL (sexp1, sexp2) -   "NOT EQUAL"
    -This takes two arguments, which may be any s-expressions, and
    returns TRUE It they are not EQUAL to each other, NIL otherwise.
    The LISP translation of X NEQUAL Y:
        (NEQUAL X Y)
    Is expanded by macros to:
        (NOT (EQUAL X Y))
    If It is compiled, NEQUAL may be abbreviated ≠ (not-equal sign).

LEQUAL (number1, number2) - "LESS THAN OR EQUAL"
    This takes two arguments, which should be numbers, and returns
    TRUE If thr first argument Is loss than Or equal to the second
    one, NIL otherwise, The LISP trrnslrtlon of X LEQUAL Y:
        (LEQUAL X Y)
    Is expanded by macros to:
        (NOT (GREATERP X Y))
    If It Is compiled,   LEQUAL   may   be   abbrev lated ≤
    (less-than-or-•auel sign),

GEQUAL (number1, number2) - "GREATER THAN OR EQUAL"
    This Is the converse of LEQUAL, It takes two arguments, whloh
    shou Id be numbers, and returns TRUE If the first argument Is
    greater than or equal to the second one, NIL otherwise, The LISP
    trrnslrtlon of X GEQUAL Y:
        (GEQUAL X Y)
    Is expanded by macros to:
        (NOT (LESSP X Y))
    If It Is compiled,   GEQUAL   may   be   abbreviated   ≥
    (greater-than-or-equal sign),

Examples of these run-time functions:

```
'(A B C D E) PRELIST 3            =       (A B C)
'(A B C D E) ↑ 3                  =       (A B C)
'(A B C D E) ↑ 10                 =       (A B C D E)
'(A 6 C D E) ↑ 0                  =       NIL

'(A B C D E) SUFLIST 3            =       (D E)
'(A B C D E) ↓ 3                  =       (D E)
'(A B C D E) ↓ 10                 =       NIL
'(A B C D E) ↓ 0                  =       (A B C D E)

'(A B C D E) ↑ 3 @ '(A B c D E) ↓ 3      = (A B C DE)
'(A B C D E) ↑ 10 @ '(A B C D E) ↓ 10    = (A B C D E)
'(A B C D E) ↑ 0 @ '(A B C D E) ↓ 0      = (A B C 0 E)

'(A B C D E)↓0 ≡    '(A B C D E)           = (A B C D E)
'(A B C D E)↓1 ≡    CDR '(A B c D E)       = (B C D E)
'(A B C D E)↓2 ≡    CDDR '(A B C D E)      = (C D E)
'(A B C D E)↓3 ≡    CDDDR '(A B C D E)     = (D E)
'(A B C D E)↓4 ≡    CDDDDR '(A 8 C D E)    = (E)
'(A B C D E)↓5 ≡    CDR  CDDDDR '(AB C D E)  = NIL

'A NEQ '8                         =       T

. SAMPLE MLISP PROGRAM - SECTION 6.1

BEGIN

% This program is Included to provide an example of the MLISP
language,   It examines several ways of writing the function REVERSE
In MLISP,   REVERSE was chosen because It Isfamiliar to most people;
It reverses the top level of a list: REVERSE '(A B C) = (C B A),

The function REVERSE may be written In many ways In MLISP,   Some of
the . ways shown here are not too efficient, but they do serve to
Illustrate different MLISP expressions,   The method used In each
function Is explained In a comment Included with the function, %

%###%
%#######   DEFINE ALL THE REVERSE [UNCTIONS   ########%
%###%

% REVERSE1 Just calls REVERSE1a with the list to be reversed and NIL.
The NIL Initializes REVERSE1a's second argument, %

EXPR REVERSE1 (L);   REVERSE1a(L,NIL);

% REVERSE1a doe8 all the work for REVERSE1,   It uses an IF expression
and a recursive call on Itself, The reverse of L la built up In the
second argument RL, %

EXPR REVERSE1a (L,RL);
    IF NULL L THEN RL ELSE REVERSE1a(CDR L,CAR L CONS RL);

% REVERSE2 also uses an IF expression and a recursive call on Itself.
In this clever but Inefficient version, the reverse of the rest of
the list L Is APPEND'ed (@) to a list containing the first element, %

EXPR REVERSE2 (L);
    IF NULL L THEN NIL ELSE REVERSE2(CDR L) @ <CAR L>;

% REVERSE3 Is an FEXPR; the arguments to It are unevaluated, It uses
a FOR expression as follows: I Is set to each member of the list L
and then Is CONS'ed onto the reversed list RL,   REVERSE3 does not use
recursion, %

```
FEXPR REVERSE3 (L);
   BEGIN  NEW RL;          % PROG variables are initialized to NIL.%
      RETURN FOR NEW I IN L DO RL ← I CONS RL;
   END;
```

% REVERSE4 is an example of a FOR expression using a numerical increment. In the operation of the loop, I IS incremented from 1 to the length of L. For each value, the I'th element of L is obtained by the [Index expression L[I] and then is CONS'ed onto the reversed list RL, %

```
EXPR REVERSE4 (L);
   BEGIN  NEW RL;
      RETURN FOR NEW I←1 TO LENGTH L DO RL ← L[I] CONS RL;
   END;
```

% PROG1 Is like PROG2, except that PROG1's value is the value of its first (rather than its second) argument. This is not a reverse function, but is used by reverse functions which follow, %

```
EXPR  PROG1 (A,B);  A;
```

% REVERSE5 is another FEXPR, It uses a WHILE expression as follows: while there IS still something left in L, the next element Is taken off and CONS'ed onto the reversed list RL, This does not use recursion, %

```
FEXPR REVERSE5 (L);
   BEGIN  NEW RL;
      RETURN WHILE L DO PROG1(RL ← CAR L CONS RL, L ← CDR L);
   END;
```

% REVERSE6 uses an UNTIL expression (PO-UNTIL), The operation of this UNTIL-loop is roughly the same a8 that of the WHILE-loop In REVERSE5, The one difference 18 that since the body of the loop gets executed before testing If there Is anything In L, an initial test must be included to take care of the trivial case where REVERSE6 Is called with NIL as its argument, This does not use recursion, %

```
EXPR REVERSE6 (L);
    IF NULL L THEN NIL ELSE
    BEGIN  NEW RL;
        RETURN DO PROG1(RL + CAR L CONS RL,L + COR L) UNTIL NULL L;
    END;
```

% **REVERSE7** uses a standard LISP function, MAPCAR, together with a LAMBDA expression. The operation of this Is very similar to that of REVERSE3. %

```
FEXPR REVERSE7 (L);
    BEGIN  NEW RL;
        MAPCAR(FUNCTION(LAMBDA(I); RL + I CONS RL), L);
        RETURN RL;
    END;
```

% Of all the methods presented, **REVERSE8** Is the most unique to MLISP. It uses a numerical **FOR**-loop, as does REVERSE4; In addition It uses index expressions on both the left and right sides of the assignment operator (+). The Index expression on the left side retrieves the I'th position In the reversed list RL, Into which is placed the LEN-N+1'st element of L, LEN Is the length of L, The first Index expression is used to obtain a "cell" or **POSITION** In RL, while the second Index expression is used to obtain the **ELEMENT** which occupies a position In L. %

```
EXPR REVERSE8 (L);
    BEGIN  NEW RL,LEN;
        LEN + LENGTH L;
        FOR NEW N+1 TO LEN DO RL[N] + L[LEN-N+1];
        RETURN RL;
    END;
```

% The LISP translation of this program Is listed In the following section. It has been printed using a program called PPRINT, an s-expression formatting (pretty-printing) Program This program Is written In MLISP and Is Included with the MLISP system. (All of the files In the MLISP system are listed In SECTION 4.3.) Note that FOR-loops, WHILE-loops and UNTIL-loops have been expanded by macros into In-line code. %

END.

, THE MLISP SCANNER - SECTION 7.1

The set of routines that returns the next "token" (identifier, number, special character, string) in the input stream is generally called the "scanner" for a language, It Is true of almost every language that the majority of compilation time Is spent In the scanner, since every character In a program has to be read In individually and some sequence of tests made on It, This Is the plight of MLISP, and the best that can be done Is to make the scanner as fast and efficient a3 possible, Lynn Quam at Stanford has developed a super fast, table-driven **READ** function for LISP 1.6. To this he has added a set of machine language functions which may be used to specify the precise syntax for a token returned by **READ**. These routines actually modify READ's internal character tables, thus giving the user a completely general table-driven scanner, The scanner for MLISP was obtained In this way, It has Increased translation speed by a factor of three (translation speed 'IS now **30004000** lines/minute), It has decreased the size of the translator as well, since using **READ** does not require any additional **LISP** functions,

Since there Is no formal writeup on Quam's READ-modifying functions, the following Is a reproduction of (parts of) Quam's informal description,

> **LISP** now uses a table driven scanner, whose table may be modified by the user for the purpose of implementing scanners for other languages, For simplicity, the functions for constructing the scanner table initially give an **ALGOL** type scanner; that Is, the ALGOL definitions for Identifiers, strings and numbers, The **ALGOL** table may be deviated from by using additional functions to Include additional characters In Identifiers, and to specify delimiters for strings,

(SCANINIT comment_start comment-end string_start string_end literally)
>   SCANINIT sets up the LISP scanner to be an **ALGOL**-type scanner with the, special delimiters tot comments and strings, MLISP calls (SCANINIT % % " " ?),

(LETTER x)
>   **LETTER** specifies to the scanner that x Is an extra-letter, and thus allows x to be In an Identifier, MLISP call3 (**LETTER** _), (**LETTER** !), (LETTER !),

(IGNORE x)
>   IGNORE specifies to the scanner that x **I3** not to be **returned as a delimiter from SCAN, but Instead will be**

Ignored. However, x will still function as a separator between identifiers and numbers. MLISP calls (IGNORE BLANK),(IGNORE CR), (IGNORE LF), (IGNORE FF), (IGNORE VT), (IGNORE TAB), (IGNORE ALTMODE).

(SCAN)

SCAN reads an atom or delimiter and sets the value of the global variable SCNVAL to the value read, and returns a number corresponding t o the syntactic type read, a 8 follows:

Syntactic Type	Value of SCAN	Value of SCNVAL
<identifier>	0	the uninterned identifier
<string>	1	the string
<number>	2	the value
<delimiter>	3	the ASCII numerical value of the delimiter

(SCANSET)

SCANSET modifies the LISP scanner In READ according to the user specifications.

(SCANRESET)

SCANRESET unmodifies the LISP scanner to its normal state, and must be called before REAP will work properly once SCANSET is used.

, THE MLISP SCANNER - SECTION 7.2

BEGIN

% fhls program presents a set of functions which Is equivalent to the
MLISP scanner,   It|s for the reference of users wanting to implement
MLISP on a LISP system without Quam's READ-modifying   funct ions. In
ardor to use these functions, the funotlon &SCAN in the MLISP
translator should be replaced by the &SCAN funotion below,   and the
other functions added where convenient.   The functions below are
written In MLISP, so their LISP translations would actually be used,

The scanner below places only two restrictions on the LISP system
(1) There must be a READCH function, which reads the next character
      In the Input stream and returns that character as Its value,

(2) There must be a READLIST funotion, which takes as Its argument a
      list of single characters and concatenates them to form an atom

These two functions are taken to be primitives, and they are used
below without further explanation,   &SCAN sets the global variables
&SCANTYPE and &SCANVAL as follows;

Syntactic Type	Value of &SCANTYPE	Value of &SCANVAL
<identifier>	0	the Identifier
<string>	1	the str lng
<number>	2	the number
<delimiter>	3	the delimiter

!NEXT_CHAR Is always set to the next character In thr Input stream
after the current token has been obtained,   .
