# A NEW APPROACH TO RECURSIVE PROGRAMS 

by<br>ZOHAR MANNA* AND ADI SHAMIR**

#### Abstract

In this paper we critically evaluate the classical least-fixedpoint approach towards recursive programs. We suggest a new approach which extracts the maximal amount of valuable information embedded in the programs. The presentation is informal, with emphasis on examples.

[^0]
## I. Introduction

The classical stack implsmsntation of recursive programs does not always give results that correspond to our naive intuitive expectations. For instance, one might expect the program

$$
F(x)<=-8 \cdot F(x)
$$

over, say, the natural numbers, to be identical to the program

$$
F(x)<==8,
$$

si nce for any number y, ©.y.y. Simi iariy, the program

$$
F(x)<==\text { if } F(x)=\theta \text { then } \theta \text { else } \theta
$$

would be expected to yield the zero function. Since the test $F(x)=8$ is irrelevant, nothing but 8 can be produced as an output. However, stack implementations and the conventional theory of programs dictate that both of these programs be undefined for allinputs. Users of recursion are so accustomed . to this implementation that they are no longer surprised at this unintuitive interpretation, and never stop to consider any alternative meanings of recursive programs.

A recursive program, such as those above, looks like an implicit functional equation relating the values of the function variable F. Such an equation may in general have many possible solution functions (fixedpoints). Since there is no unique solution, the semantics of recursive programs, is selected rather than implied. The classical stack implementation yields one soiutlon, the least defined fixedpoint of the program. As we have seen above, the blind selection of the least defined solution is inadequate, because a recursive program often contain8 more information than this solution exhibits.

In this paper we suggest the selection of a different and more defined solution, which always exists and which contain8 as much information as possible,

In Section II we discuss various possible approaches towards recursive programs, in an attempt to characterize the "best" one. On the basis of, this discussionwe introduce our new optimal fixedpoint approach in Section III, which is exemp Iifiedin Section IV. Various tschnlquss for proving properties of optimal fixedpoints are presented in Section V.

Th is paper is an informal exposition of the optimal fixedpoint thsory, More formal treatment is given in Manna and Shamir [1975] and Shamir [1976].

## II. Recursive Programs and Their Fixedpoints

Consider, as a typical example, the following recursive program P1 over the natural numbers [see note (i)]:

P1: $F(x, y)<==$ if $x=0$ then $y$ else $F(F(x, y-1), F(x-1, y))$.

Any solution function to this program must satisfy the relations dictated by the program, i . e.,
(a) $F(\theta, y)=y$ for all $y$, and
(b) $F(x, y)=F(F(x, y-1), F(x-1, y))$ for all $x \neq 0$ and ail $y$.

Let us analyze what functions satisfy these two conditions.
The main part of this program is the functional

```
T[F]: if x=0 then y else F(F(x,y-1),F(x-1,y)),
```

in which the symbol $F$ is considered as a fuction variable. Given any partial function $f(x, y)$, the result of substituting for foides a neu partial function, denoted by $\boldsymbol{T}[f]$. For example, if us substitute the function

$$
f(x, y)=y
$$

for $F(x, y)$, we obtain the function

$$
\text { - } \begin{aligned}
T[f](x, y) & =\text { if } x=0 \text { then } y \text { else } f(f(x, y-1), f(x-1, y)) \\
& =\text { if } x-8 \text { then } y \text { else } f(y-1, y)
\end{aligned}
$$

= $y$. .

Thus, : the function $f(x, y)$ has the interesting property that $f(x, y)=T[f](x, y)$, that is, $f$ is a solution function to the functional equation $F(x, y)=f[F](x, y)$. Since $f$ does not change under the app i icat ion of $\boldsymbol{T}$, $\mathrm{t} \boldsymbol{\mathrm { i }}$ \% said to be a fixedpoint of the given recursive program.

An entirely different function which is a fixedpoint of the program is:

$$
g(x, y)=\max (x, y)
$$

Substituting g for $F$ in. $\mathrm{f}[\mathrm{F}]$, we obtain:

$$
T[g](x, y)=\{f x=8 \text { then } y \text { else } \max (\max (x, y-1), \max (x-1, y)) \text {. }
$$

By the def ini tion of max, this can be simpi ified to:

$$
\begin{aligned}
\tau[g](x, y) & =\text { if } x=0 \text { then } y \text { else } \max (x, y-1, x-1, y) \\
& =\text { if } x-0 \text { then } \max (x, y) \text { else } \max (x, y) \\
& =\max (x, y) .
\end{aligned}
$$

Thus $g(x, y)$ is a fixedpoint of the recursive program P1.
Yet another example of a fixedpoint is the partial function:

$$
l(x, y)=\text { if } x-0 \text { then } y \text { else undefined. }
$$

To show that this function is indeed a fixedpoint of our recursive program, we substitute $l$ in $\boldsymbol{r}$, treating undefined as any other value. For this purpose we make the general assumption that all functions and predicates appearing in $\boldsymbol{r}$ are "natural ly extended,' in the sense that they are undefined whenever at last one . of their arguments is undefined. Thus, we haves

$$
\begin{aligned}
f[l](x, y)= & \text { if } x=8 \text { then } y \text { else } l(l(x, y-1), l(x-1, y)) \\
& =\text { if } x=\theta \text { then } y \text { else } \\
& l(\text { if } x=8 \text { then } y-l \text { else undefined, } l(x-1, y)) \\
& =\text { if } x=0 \text { then } y \text { else } l(u n d e f i n e d, l(x-1, y)) \\
& =\text { if } x-0 \text { then } y \text { else } \\
& \text { if } u n d e f i n e d=\theta \text { then } l(x-1, y) \text { else undefined } \\
& =\text { if } x=0 \text { then } y \text { else undefined. }
\end{aligned}
$$

These three functions do not exhaust the set of allfixedpoints of the program. An example of an 'infinite cl888 of fixedpoints (indexed by the function a over the natural numbers) ist

$$
n_{a}(x, y)=\text { if } x=0 \text { then } y \text { else } a(x) \text {. }
$$

A function $h_{a}(x, y)$ can be shown to be a $f$ ixedpoint of the program, provided that the function $a(n)$ satisfies:

$$
a(n), 0 \text { and } a(a(n))=a(n) \text { for ail } n>0 \text {. }
$$

Examples of functions' satisfying this condition are the identity function, any non-zero constant function, or the function which assigns to any natural number $n$ its greatest prime factor.

There are actual ly infinitely many more distinct fixedpoints, the exact characterization of which is quite complicated. We can thus see that the set of al fixedpoints of the program may contain many functions with extremely diversified behavior. All these functions can be considered as "solutions" to the equation represented by our recursive program.

Some of these fixedpoints are related by the "less defined or equal" relation. We say that a function $r(x, y)$ is less defined or equal to $s(x, y)$, or that $s(x, y)$ is more defined or equal to $r(x, y)$, if for any pair of natural numbers $(a, b)$, if $r(a, b)$ is defined than $s(a, b)$ is also defined and has the same value; thus, either $r(a, b)$ is undefined or else $r(a, b)=s(a, b)$. Note that a function $r(x, y)$ may be neither "less defined or equal" nor "more defined or equal" to $s(x, y)$.

This relationintroduces some structure into the set of ail fixedpoints of a recursive' program. A fixedpoint is called least (defined) if it is less defined or equal to any other fixedpoint of the program. Dually, a fixedpoint is called greatest (defined) ifitis more def ined or equal to any other $\mathbf{f} \mathbf{i}$ xedpoint.

Among the f ixedpoints of the program P 1 , the fixedpoint:
$l(x, y)=$ if $x=0$ then $y$ else undefined
stands out. Since any $f$ ixedpoint of $P 1$ must be defined as $y$ for $x=8$, it is clear ly the program's least f ixedpoint.

Least fixedpoints of recursive programs have long attracted the attention of computer science, theoreticians for three main reasons (see, e.g., Manna [1974)):
(a) Any recursive program must have a (unique) least $f$ ixedpoint. Thus the least fixedpoint can be used to unambiguousiy define the "meaning" of recursive programs,
(b) The classical stack implementation of recursive programs computes the least fixedpoint of the program.
(c) There are powerful method8 for proving properties of the least fixedpoint of programs.

As a result, the least fixedpoint was chosen as the "proper" solution of recursive programs and other fixedpoints were absolutely discarded by researchers from further consideration. However, we have an important objection to thie choice; it contradicts the intuitive concept that the more defined the solution,
the more valuable itis. Indeed, there are many recursive programs for which the least fixedpoint does not contain all the useful information embedded in the program, information which is contained in more defined fixedpoints.

Consider, for example, the following recursive program P2 for solving the discrete form of the Laplace equationwhere $F(x, y)$ maps pairs of integers in [0,100] $\times[0,180]$ into reals:

$$
\begin{aligned}
\text { P2: } F(x, y)= & \text { if } x-8 \text { then } 2 y \\
& \text { else if } x-180 \text { then } 3 y+388 \\
& \text { else if } y=8 \text { then } 3 x \\
& \text { else if } y-108 \text { then } 4 x+288 \\
& \text { else }[F(x-1, y)+F(x, y-1)+F(x+1, y)+F(x, y+1)] / 4 .
\end{aligned}
$$

This recursive program has exactly two fixedpointst

$$
f(x, y)= \begin{cases}2 y & \text { if } x=8 \\ 3 y+388 & \text { if } x-100 \\ 3 x & \text { if } y=8 \\ 4 x+288 & \text { if } y-108 \\ \text { undefined } & 0 \text { t herw ise }\end{cases}
$$

and

$$
g(x, y)=3 x+2 y+(x, y) / 188 \text { f o r } 8 \leq x, y \leq 180 .
$$

There is no doubt that the second (totally defined) fixedpoint $g(x, y)$ contains much more valuable information than the (mostly undefined) function $f(x, y)$. Moreover, it is quite obvious that any programmer writing such arecursive program unconsciously thinks about the function $g(x, y)$ as the "solution" of the functional equation represented by the program, Thus, the arbitrary select ion of the least 'fixedpoint as the "proper solution" seems a poor choice in thie case.

This example might suggest a turn to the other extreme - considering greatest fixedpoints rather than least fixedpoints. Unfortunately, there are many programs for. which there is no such greatest fixedpoint, as program P1 shows: Thereis no function which is more defined than aii the fixedpoints exhibited,

A more modest approach could be the selection of a maximal flxedpoint,l.e., a fixedpoint which is not less dsf ined than any other fixedpoint. However, there are difficulties with this choice too. While any recursive program has such a f ixedpoint, it may have more than one. This is demonstrated by program P1, in which the functions $f(x, y), g(x, y)$ and $h_{a}(x, y)$ are al i examples of total, a $n d$ therefore maximal, fixedpoints of P1. This indicates that P1 is a n "underdefined" recurs $i$ ve program - the relations stated between values of $F$ for various arguments $(x, y)$ are not sufficient to uniquely determine one defined value of the
fixedpoint. Thus a randomly chosen maximal fixedpoint is by no means superior to the least fixedpoint $l(x, y)$ in this case.

An artificial example which illustrates this problem is:

$$
\text { P3: } \quad F(x)<=F(x)
$$

over, say, the set of the natural numbers. Any partial function over the natural numbers is clearly a fixedpoint of this extremely "underdefined" program. The least fixedpoint of P3 is the total ly undefined function, and every total function over the natural numbers is a maximal fixedpoint. In such a case, the least $f$ ixedpoint seems the most appropriate solution, since no other fixedpoint can be considered a more "valuable" solution of this program.

## III. The Optimal Fixedpoint

Thus far we have objected to the classical least fixedpoint and the proposed greatest and maximal -fixedpoint approaches to recursive programs. We now suggest a new approach -- the "optimal fixedpoint approach". 1t combines the nice properties of all the above approaches in that the fixedpoint selected always uniquely exists, and it suppl ies the maximal amount of valuable information embedded in the program. Thus in the three examples considered so far, the new approach wi I I select the least fixedpoint in the "underdef i ned" programs P1 and P3, but wi IIselect the desired total fixedpoint (which differs from the least fixedpoint) in the Laplace programP2.

In order to develop the new approach we first introduce the notion of "consistency". Two functions are said to be consistent if they have identical values for any argument for which both are defined. For example, let

$$
\begin{aligned}
& f_{1}(x)= \begin{cases}0 & \text { if } x-0 \\
\text { undefined } & \text { if } x-i \\
0 . & \text { otherwise }\end{cases} \\
& f_{2}(x)= \begin{cases}0 & \text { if } x=0 \\
1 & \text { if } x-1 \\
\text { undefined } & \text { otherwise }\end{cases} \\
& f_{3}(x)= \begin{cases}8 & \text { if } x-0 \\
2 & \text { if } x-1 \\
\text { undefined } & \text { otherwise }\end{cases}
\end{aligned}
$$

Then $f_{1}$ and $f_{2}$ are consistent, as are $f_{1}$ and $f_{3}$. However, $f_{2}$ and $f_{3}$ are $n$ ot consistent, since for $x-l$ both are def insd and have different values. Note that
no two of these functions are related by the "less defined or equal" relation.
Two consistent functions can be regarded as being "approximately the same": One function may be defined for several arguments at which the other is undefined, and vice versa; but the two functions cannot have contradictory defined values. They can be considered as two incomplete representations of the same knouledge, and one can define a function which is morë defined than both of them, thus being superior to both partial representations.

We now 'def $i$ ne afixedpoint $f$ of a program $P$ to be fxp-consistent iffie cone latent with any other fixedpoint $g$ of $P$. That $i s$, whenever $f i e d e f i n e d, ~ e a y ~ f(x)=a$, then for any other fixedpoint $g$, either $g(x)$ is undefined or $g(x)=a$. Thus the value a is implicitly defined by the program as the only possible defined solution at $x$. Every recur8ive program has at leastonefxp-consistent f ixedpoint, since the least fixedpoint of the program is less defined than (and thus consistent with) any other fixedpoint of the program. Thus, the classical least fixedpoint is one of these valuable fixedpoints, but only one of many.

The fxp-consistent fixsdpointe can be considered as the only genuine solutions of a recurs $i$ ve program, since only they contain uniquely determined values. Wecan thus concentrate our attention on the subset of fxp-consistentfixedpoints rather . than on the eet of al ifixedpoints of the program. In this restricted set of solutions we are natural ly intereeted in maximal ly defined eolutione of. the program. Whi le the greatest fixedpoint approach wae not applicable to the set of all fixedpoints of the program, we now fortunately have fees note (ii)]:

## Basic Theorem: The set of all fxp-consistent fixedpoints always contains a (unique) greatest element.

Let us now look at the set of fixedpoints from a different point of view. . Previously, we discussed the possibility of selecting a maximal fixedpoint ae the "proper" solution of the program. This approach wao not applicable, since the program may have infinitely many such solution8 with no information common to all of them, and no one of which eeeme superior to the others. A natural way to resolve this problem is to find a fixedpoint which extracts the unanimity among these maxim\& fixedpoints, thus being a satisfactory representative of all of them. Such a fixedpoint can be obtained by considering the fixsdpointe which are lees defined than al I the maximal fixedpoints. For theee fixedpointe we again have [see note (iii)]:

Basic Theorem: The set of fixedpoints which are less defined than all inaximal fixedpoints of the program, has a (unique) greatest element.

We have thus arrived at two possible definitions of the "most desired solution" of a recursive program, the first by ascending as much as possible from the least fixedpoint in the set of fxp-consistent fixedpointe, and the second by descending from the maximal $f$ ixedpointe.

It is quite natural to relate these. two "desired solutions" of a recursive program. Surprisingly enough, these two fixedpoints always coincide, and we call the f ixedpoint thus defined the optimal fixedpoint of the program.

By the definition of, the optimal fixedpoint, it follows that any recursive program has a unique optimal fixedpoint. If the program hae only one fixedpoint which, is fxp-consistent, the optimal fixedpoint coincides with the classical least fixedpoint. On the other hand, if the program has a unique maximal f ixedpoint, the optimal fixedpoint coincides with. it. In all other cases, the optimal fixedpoint "floats" somewhere in the set of al l ixedpointe. We illustrate this with the following diagram (see Fig. 11, which eummarizes some of the structural properties of the set of fixedpoints of recursive programs. In this diagram an upper section (Fig. 2A) represents the set of al I fixedpointe which are more defined or equal to. f; similarly, a lower section (Pig. 2B) represents the set of allfixedpoints which are lees defined or equal to $f$. The "strategicposit ion" of the optimal fixedpoint is clearly visible.

## IV. A Detailed Example

Consider the following family of recursive programs over the natural numbersi

$$
P_{i, j}: \quad F(x)<==\text { if } x=0 \text { then i else } j \cdot F(F(x-1)) .
$$

We shal I investigate the structure of the set of fixedpoints for a few recursive pcograme in this family, thus illustrating the behavior of the optimal fixedpoint approach in various eituatibns. In order to systematically analyze the possible values of fixedpoints for some $x-a$, we evaluate the term $F(a)$ by repeatedly substi tut ing $\boldsymbol{r}[F]$ for var ioue occurrences of $F$. Note that we make use of the fact that $F$ represents a fixedpoint of the program, but not neceeeari lythe least fixedpoint or the optimal fixedpoint.

Programs $P_{0,1}$ :

$$
F(x)<-=\text { if } x=0 \text { then } 0 \text { else } j \cdot F(F(x-1)) \text {. }
$$

Let us analyze the possible values of $F$ for successive arguments $x$ :

Fig. 1. The fixedpoints of a recursive program .

Fig. 2A

Fig. 2 B

```
\(F(8)=\) if \(\theta=8\) then \(\theta\) else \(j \cdot F(F(0-1))=8\)
\(\mathrm{F}(1)=\) if \(1-0\) then 0 else \(\mathrm{j} \cdot \mathrm{F}(\mathrm{F}(1-1))\)
    \(=j \cdot F(F(\theta))=j \cdot F(\theta)=j \cdot \theta=\theta\)
\(F(2)=\) if 2-0 then \(\theta\) else \(\mathrm{j} \cdot \mathrm{F}(\mathrm{F}(2-1))\)
    \(-j \cdot F(F(1))=j \cdot F(0)=j \cdot \theta=0\)
```

It can be eaei ly shown (by induction) that $F(x)=8$ for any natural number $x$, Thus for any $\mathbf{j}$, the prbgram $P_{\theta, j}$ has exactly one fixedpointt
$f(x)=8$ for any natural number $x$.
It is clearly the program's least fixedpoint as well as the program's optimal f ixedpoint.

The behavior of the programs changes draet ically when we take i to be 1 rather than 0 .

Program $\mathbf{P}_{1,0}$ :
$F(x)<==$ if $x=8$ then 1 else $8 \cdot F(F(x-1) 3$.

The value of $F(8)$ is clearly 1 , by a direct application of the recursive definition. For x-I, however, we get:
$F(1)=$ if $1-0$ then 1 else $8 \cdot F(F(1-1))$
$=\theta \cdot F(F(\theta))=8 \cdot F(1)$.

We now have exactly two possible values for $F(1)$ :
$F(1)=$ undefined or $F(1)=0$.

Selecting the first poeeibi lity, $F(1)=$ undefined, we obtain:
$F(2)=$ if $2=0$ then 1 else $8 \cdot F(F(2-1))$
= $0 \cdot F(F(1))=8 \cdot F$ (undefined)
= © (if undefined-0 then 1 else $\boldsymbol{0} \cdot \mathbf{F}$ (F (undefined-1)))

- $\boldsymbol{\theta} \cdot$ undefined $=$ undefined .

Continuing in this way, we get the fixedpoint:

$$
f(x)= \begin{cases}1 & \text { if } x-0 \\ \text { undefined } & \text { otherwise } .\end{cases}
$$

However, if we select the second possibility, $F(1)=8$, we havo to con $t$ inuo in the fol lowing way:

$$
\begin{aligned}
F(2) & =\text { if } 2-8 \text { then } 1 \text { else } \theta \cdot F(F(2-1)) \\
& =\theta \cdot F(F(1))=\theta \cdot F(\theta) . \theta \cdot 1=\theta,
\end{aligned}
$$

and $s o$ on. We thus get the fixedpoint:

$$
g(x)= \begin{cases}1 . & \text { if } \quad x-8 \\ 0 & \text { otheruiee } .\end{cases}
$$

The functions $f(x)$ and $g(x)$ are clearly the only possible fixedpoints of the program. Since $f(x)$ is lees defined than $g(x)$, $f(x)$ is $t h$ e program's least f ixedpoint whi leg(x)is the program's optimal fixedpoint.

Program $\mathbf{P}_{\mathbf{1 , 1}}$ :
$F(x)<==$ i $f x=0$ then 1 else $F(F(x-1))$.

The value of $F(8)$ is necessarily 1 . Evaluating $F(1)$, we get:

```
F(1)=if 1=0 then 1 else F(F(1-1))
        = F(F(0))=F(1) ,
```

and thus any natural number (aswellas the value undefined)is asolution of this equation. If we choose $F(1)=u n d e f i n e d$, we get (exactly as in program $P_{1,0}$ ) the f ixedpointt

Since any other fixedpoint of $P_{1,1}$ must also be 1 for $x-8$, $f(x)$ isclearly the program's least f ixedpoint.

Suppose we choose $F(1)=0$. We then continuewiths

```
F(2) = if 2=0 then 1 else F(F(2-1))
    =F(F(1))=F(0)=1
F(3) = if 3-0 then 1 else F (F (3-1))
    - F(F(2))=F(1)=0
```

and so on. We thus get the fixedpoint:

$$
g(x) \begin{cases}1 & \text { if } x \text { ieeven } \\ 0 & \text { if } x \text { is odd } .\end{cases}
$$

If wetake $F(1)=1$, we obtain:

$$
\begin{aligned}
F(2) & =\text { if } 2=0 \text { then } 1 \text { else } F(F(2-1)) \\
& =F(F(1))=F(1)=1,
\end{aligned}
$$

and so on. We thus obtain the fixedpoint:

```
h(x) = I for any natural number x .
```

If we take $F(1)=2$, we get:

$$
\begin{aligned}
F(2) & =\text { if } 2=8 \text { then } 1 \text { else } F(F(2-1)) \\
& =F(F(1))=F(2)
\end{aligned}
$$

and again we may choose any desired value for $\mathcal{F}(2)$ (including the value undefined)

It- is possible to continue this detailed analysis and find infinitely many more fixedpoints of $P_{1,1}$. But in order to characterize the optimal fixedpoint of this program it suffices to consider just one more fixedpoint:

```
- k(x) = x+1 for any natural number x .
```

Since the optimal fixedpoint should be less defined than both maximal fixedpoints $h(x)$ a $n d k(x)$, it cannot be defined for any $x>8$ (for any such $x$ both $h(x)$ and $k(x)$ are defined and $h(x) w(x))$. Therefore the program's optimal fixedpoint coincides in this case with the program's least fixedpoint $f(x)$.

Program $\mathrm{P}_{1,2}$

$$
F(x)<==\text { if } x=0 \text { then } 1 \text { else } 2 \cdot F(F(x-1)) \text {. }
$$

As before, al 1 f ixedpoints of $P_{1,2}$ are defined as 1 for $x-0$. For $x=1$ we have
$F(1)=i f 1=8$ then 1 else $2 \cdot F(F(8))=2 \cdot F(1)$.

We have arrived at an equation (for the value of $F(1)$ ) which hasexactly two solutions:

$$
F(1)=\text { undefined or } F(1) \cdot 8 \text {. }
$$

If we decide to take the value $F(1)=$ undefined, we again get the fixedpoints

$$
f(x)= \begin{cases}1 & \text { If } x-e \\ \text { undefined } & \text { ot herwise }\end{cases}
$$

which is the program'8 least fixedpoint.
Choosing the other possibility, i.e., $F(1)=0$, we gets

$$
\begin{aligned}
& F(2)=2 \cdot F(F(1))=2 \cdot F(8)=2, \\
& F(3)=2 \cdot F(F(2))=2 \cdot F(2)=4,
\end{aligned}
$$

and final ly:

$$
F(4)=2 \cdot F(F(3))=2 \cdot F(4) .
$$

The values 'for $F(2)$ and $F(3)$ were implied, once we chose $F(1)=0$. But for $F(4)$, we again havd to choose between the $t w o$ possible solutions of the equation, namely,

$$
F(4)=\text { undefined } o r F(4)=0 .
$$

If we. choose $F(4)$ undefined, then an argument similar to the one usedpreviously shows that for any $x>4, F(x)=$ undefined. Thus we have the $f$ ixedpoint

$$
g(x)= \begin{cases}1 & \text { if } x-0 \\ 0 & \text { if } x-1 \\ 2 & \text { if } x=2 \\ 4 & \text { if } x-3 \\ \text { undefined } & \text { otherwise }\end{cases}
$$

However, if we choose $F(4)=\varnothing$, we must continue as follows
$F(5)=2 \cdot F(F(4))=2 \cdot F(8)=2$
$F(6)=2 \cdot F(F(5))=2 \cdot F(2)=4$
$F(7)=2 \cdot F(F(6))=2 \cdot F(4)=8$,
and so on. The periodic function thus obtained is defined for any natural number $x$ as:
$h(x)=\left\{\begin{array}{ll}1 & \text { if } x=8 \\ 8 & \text { if } x=1+3 i \\ 2 & \text { if } x=2+3 i \\ 4 & \text { if } x=3+3 i\end{array}\right\} i=0,1,2, \ldots$
To sum up, the recursive program $P_{1,2}$ has exactly threefixedpoints, each generated by a differ\&it selection of a solution to the above equations:

$$
\begin{aligned}
& f(x)= \begin{cases}1 & \text { if } x-8 \\
\text { undefined } & \text { otherwise }\end{cases} \\
& g(x)= \begin{cases}1 & \text { if } x=0 \\
0 & \text { if } x=1 \\
2 & \text { if } x=2 \\
4 & \text { if } x-3 \\
\text { undefined } & \text { other } w \text { i se }\end{cases} \\
& h(x)=\left\{\begin{array}{ll}
1 & \text { if } x=0 \\
0 & \text { if } x=1+3 i \\
2 & \text { if } x=2+3 i \\
4 & \text { if } x=3+3 i
\end{array}\right\} i=0,1,2, \ldots
\end{aligned}
$$

Note that $f$ is less defined than $g$ and $g$ is less defined than $h$. The only maximal fixedpoint of this program is $h$, and thus $l t$ is also the program's optimal fixedpoint.

Program $P_{1,3}$ :
$F(x)<==$ if $x=0$ then 1 else $3 \cdot F(F(x-1))$.
As before, $F(\theta)=1$, and there are exactly two possible values for $F(1)$ :

$$
F(1)=\text { undefined } \operatorname{ar} F(1)=8 \text {. }
$$

The f'irdt possibi lity leads to the same leastfixedpoint as beforas

$$
f(x)= \begin{cases}1 & \text { if } x=0 \\ \text { undefined } & \text { otherui se }\end{cases}
$$

The second possibility leads to:

$$
\begin{aligned}
& F(2)=3 \cdot F(F(1))=3 \cdot F(8)=3, \\
& F(3)=3 \cdot F(3) .
\end{aligned}
$$

Here we have the same choice once more,

$$
F(3)=\text { undefined or } F(3)=8 .
$$

If we choose $F(3)$ undefined we get the fixedpoint

$$
g(x)=\left\{\begin{array}{lc}
1 & \text { if } X-0 \\
0 & \text { if } x=1 \\
3 & \text { if } X-2 \\
\text { undefined } & \text { otherwise }
\end{array}\right.
$$

However, if we choose $\mathbf{F ( 3 )}=8$ we continue with

$$
\begin{aligned}
& F(4)=3 \cdot F(F(3))=3 \cdot F(0)=3, \\
& F(5)=3 \cdot F(F(4))=3 \cdot F(3)=8,
\end{aligned}
$$

and so on, and we obtain the third possible fixedpoint:

$$
h(x)= \begin{cases}1 & \text { if } x-8 \\ 0 & \text { if } x=1+2 i \quad i=0,1,2, \ldots \\ 3 & \text { if } x=2+2 i_{3}\end{cases}
$$

The optimal fixedpoint of $P_{1,3}$ is clearly $h(x)$.

Program $\mathrm{P}_{1,4}$ :
$F(x)<==$ if $x-0$ then 1 else $4 \cdot F(F(x-1))$.

This program behaves entirely differently from the cases considered previously. For $x-0$, we still get $F(\theta)=1$. For $x-1$, we get:

```
F(1)=4\cdotF(F(0))=4\cdotF(1),
```

and we have the same choice as before,

```
F(1)= undefined or F(1)=0
```

If we take $F(1)=0$, we continue with:

$$
F(2)=4 \cdot F(F(1))=4 \cdot F(0)=4,
$$

and therefore:

$$
F(3)=4 \cdot F(F(2))=4 \cdot F(4)=16 \cdot F(F(3)) .
$$

Here we encounter a new problem! We do get an equation for the value of $F(3)$, but $F(3)$ is contained in another occurrence of $F$ on the righthand side of the equation. Since we do not know the global behavior of this function, we cannot simply solve this equation. However, based upon results in number theory, it can be shown that any fixedpoint of this program must be undefined for $x \geq 3$, Therefore, the program $P_{1,4}$ has exactly two fixedpoints:

$$
f(x)=\left\{\begin{array}{lr}
1 & \text { if X-8 } \\
\text { undefined } & \text { other-u i se }
\end{array}\right.
$$

and

$$
g(x)=\left\{\begin{array}{lc}
1 & \text { i f } X-0 \\
0 & \text { if } x=1 \\
4 & \text { if } X-2 \\
\text { undefined } & \text { otherwise } .
\end{array}\right.
$$

Since $f$ is less defined than $g$, $f$ is the program'8 least fixedpoint and $g$ is the program'e optimail (and. maximal) fixedpoint. In contrast to programs $P_{1,0}, P_{1,2}$ and $P_{1,3}$, the optimal fixedpoint ls not a total function, even though it isstill more defined than the least fixedpoint.

Final ly, we consider

$$
F(x)<=- \text { if } x=0 \text { then } 1 \text { else } 5 \cdot F(F(x-1)) \text {. }
$$

For $x=0$ we $\mathrm{c} I$ ear I $y$ have $F(8)-1$. For $x=1$, we have, as usua 1 , the choice between $F(1)$-undefined and $F(1)=8$. If we take the second possibility, we get $F(2)=5$, The difficulty arises when considering the possible values of $F(3)$ :

$$
F(3)=5 \cdot F(F(2))=5 \cdot F(5)=25 \cdot F(F(4))=25 \cdot F(5 \cdot F(F(3))) .
$$

This equation is too difficult to be immediately solved.
Based upon cons idsrat ions uhich are beyond the scope of thlepaper, we can find the fol lowing two fixedpoints of $P_{1,5}$ d

$$
g_{1}(x)=\left\{\begin{array}{ll}
1 & \text { if } x-0 \\
0 & \text { if } x=1+2 i \\
5 & \text { if } x=2+2 i
\end{array}\right\} \quad i=0,1,2, \ldots
$$

and

$$
g_{2}(x)=\left\{\begin{array}{ll}
1 & \text { if } x=8 \\
0 & \text { if } x=1+3 i \\
5 & \text { if } x=2+3 i \\
25 & \text { if } x=3+3 i
\end{array}\right\} \quad i=8,1,2, \ldots
$$

The optimal fixedpoint must be less defined than both of these two total (and therefore maximal) fixedpoints, so it can be defined only at argument8 of the form $x=1+6 i$ and $x=2+6 i$, for $i=8,1,2, \ldots$. However, the function thus obtained is not a fixedpoint of the program (e.g., try $x-7$ ). It can be shown that the only two fixedpoints of $P_{1,5}$ uhich are less defined than this function are:

$$
f(x)= \begin{cases}1 & \text { if } x-0 \\ \text { undefined } & \text { otherwi se }\end{cases}
$$

and

$$
h(x)= \begin{cases}1 & \text { if } x-8 \\ 0 & \text { if } x=1 \\ 5 & \text { if } X-2 \\ \text { undefined } & \text { other u ise }\end{cases}
$$

The function $f(x)$ is clearly the program'8 least fixedpoint. The fixedpointh(x) is $\mathbf{f x p}$-consistent, since all it8 values are uniquely determined by the equations.

Since the optimal fixedpoint must be either $f(x)$ or $h(x)$, and the more dsf ined function $h(x)$ is fxp-consistent, $h(x)$ is the program's optimal fixedpoint. Note
the similarity between the optimal fixedpoints of $P_{1,4}$ and $P_{1,5}$ - both are defined only for $X-0, x=1$ and $x=2$; in $P_{1,4}$ this is due to the lack of possible $f$ ixedpoints, whi lo in $P_{1,5}$ it is due to their multiplicity.

One could continue to check al l programs $P_{1, j}$ with $j$ greater than 5 . However, we believe that the preceding examples sufficiently illustrate the variety of possible cases in the new optimal fixedpoint approach. It is especial ly interesting to note that al though the least fixedpoint of al l programs $P_{1, j}$ is the same, the sets of al Ifixedpoints, as well as the optimal fixedpointe, of these programs differ widely. We summarize this situation in Fig. 3, where we exhibit the sets of fixedpoints of programs $P_{1,0}$ to $P_{1,5}$. The least fixedpoint of any such program is represented by the lowest dot, while the optimal fixedpoint is represented by the dot surrounded by a circle.

In the example8 considered so far, various techniques were used to find the correct value of the optimal fixedpoint. Some of these techniques are easily mechanizable, uhi le others require deep mathematical knowledge. Unlike the least fixedpoint of a recursive program, the optimal fixedpolnt need not be a computable function. Thus there cannot be a "complete" computation rule which always computes the optimal fixedpoint, but we can still hope to find good computation technique8 'uhich are applicable to large subsets of commonlyused programs. The examples discussed in this section give the flavor of a few such techniques.

## V. Proof Techniques

In this section weillustrate several techniques for proving properties of optimal f lxedpoints. We wish to show that optimal fixedpoint $f$ of a given
 fixedpoint. The property $Q$ is a functional predicate, uhich may characterize the overall behavior of $f$. For example, Q[f] can state that fis a total function, or that $f$ equals some given function $g$, or that $f$ is monotonically increasing over some ordered domain, etc.

General ly speaking, there are three elements involved in the process of proving properties of fixedpointst $A$ function $f$, a domain $D$, and a desired property $\mathbb{Q}$. Any one of these three elements can be used as the basis for induction,

The two classical method8 for proving properties of least fixedpointsuse induct ion on the function and on the domain, In the computational induction met hod (deBakker and Scott [1969]), one first proves the property Q over D for a very simple function $f_{0}$, and then successively treats better approximations $f_{i}$ of $\mathbf{f}$.

In the structural induction method (Burs tallel9691) one uses induc tion over the elements of the domain $D$, leaving $f$ and $Q$ unchanged.

While these two general methods, appropriately modified, can also be used to prove properties of the optimal fixedpoint in some cases, we suggest a new induction method (called assertion induction) which uses the property 0 am the basis for induction. Even though this third type of induction ha8 been totally ignored in the least fixedpoint approach, it turns out to be a very useful technique in the optimal fixedpoint approach.

What we actually prove in the assertion induction method is that any fixedpoint $f$ of the program belonging' to some given subset $S$ of partial function8 ham the property $Q[f]$. The fact that the optimal fixedpoint gpossesses the desired property is derived either as a special case (ifge $S$ ), or as a result of some further argumentation (based on the definition of $g$ as the greatest fixedpoint which is fxp-consistent).

Note that $S$ may contain functions which are not fixedpoints of the program, and these functions need not have the property 0 . The assertion induction method only shows that al $l$ functions in $S$ which are fixedpoints of the program have proper ty $Q$. The role of the subset $S$ is to rule out certain unwanted fixedpoints Which do not have the desired property 0 .

## The Assertion Induction Method

Given: A recursive program $P: F(x)<=\mathbb{T}[F](x)$, a property $Q[F]$, and a subset $S$ of partial functions.

Coal: To prove that $Q[f]$ holds for any fixedpoint $f$ of $P$ such that $f \in S$.
$M$ ethod: Find a sequence of predicates $Q_{i}[F], i=0,1,2, \ldots$ such that:
(a) $a_{0}[f]$ holds for any $f \in S$.
 holds.
(c) For any $f \in S$, if $Q_{i}[f]$ holds for all $i$, then $Q[f]$ aieo holds.

This method can be justified by the following arguments By part (e), any fixedpoint $f \in S$ ha8 property $\mathrm{a}_{\mathrm{\theta}}[f]$. By part (b), if a function $f \in S$ ham property
$\mathrm{Q}_{\mathrm{i}}[f]$, and $T[f] \in S$, then $T[f]$ has property $\mathrm{Q}_{\mathrm{i} 1}[\mathrm{f}[f]]$. But if fis afixedpoint, thentar[f] $80 \boldsymbol{T}[f] \in S$, and $f$ has property $Q_{i+1}[f]$. By induction, any fixedpoint $f \in S$ has $t h e p r o p e r t i e s Q_{i}[f]$ for $i=0,1,2, \ldots$. Thus, part (c)implies that f hae property $Q[f]$. Note that since $f$ is replaced by $T[f]$ in the induction step, any $f$ which is not a fixedpoint of $r$ is not guaranteed to have all the properties $Q_{i}$.

We illustrate this method with the foilouing recursive program over the natural numbers:

P4: $F(x)<==$ if $F(x+1)>0$ then $F(x+1)+1$ else 8 .

The least fixedpoint of this program is everywhere undefined. We would like to prove that the optimal flxedpoint of this program is the constant function
$f(x)=8$ for any natural number $x$.

We first prove two propertiee of the fixedpointe of P 4 which enable us to properly choose the subset $S$ of partial functionat
(i) For any fixedpoint $f$ of $\boldsymbol{P} \mathbf{4}$ and for any natural number $\boldsymbol{x}$, $f(x+1)$ is undefined if and only if $f(x)$ is undefined.

To show this, assumethat $f(x+1)$ is undefined; then clearly $T[f](x)=$ if $f(x+1)>8$ then $f(x+1)$ else $\boldsymbol{\theta}$ cannot bedefined. Since $f(x)=\tau[f](x), f(x)$ is alsoundefined. On the other hand, if, $f(x+1)$ is defined, then $r[f](x)$ is also defined, and since $f(x)=[f](x), f(x)$ is defined.
(ii) For any fixedpoint $f$ of $\boldsymbol{P 4}$ and for any natural number $\boldsymbol{x}$, $f(x+1)=0$ if and only if $f(x)=0$.

Th is can be shown in exactly the same way a8 in part (i) above.
These two, properties characterize two possiblefixedpoints of the program P4:f which i a everywhere undefined and $\mathbf{g}$ which iseverywhere zero. Our aim now it to show that the recursive program ha8 no other fixedpoints, and therefore whilef is the program'sleast fixedpoint, gis the program's optimal fixedpoint.

The above two proper ties imply that a n y fixedpoint of P 4 is eithertotally defined or total ly undefined, and that for any total fixedpoint $h$, either $h(x)=\theta$ for all $x$ or $h(x) \notin \theta$ for all $x$. Therefore we define $S$ as the set al lotal functions which are everywhere greater than zero, and try to prove that $P 4$ has no fixedpoint in $S$.

In order to achieve this, we formal ly define the predicate $Q[f]$ to be always "false". The sequence of intermediate predicates we use isr

$$
Q_{i}[f] \text { is true if and only if } f(x)>i \text { for all natural numbers } x
$$

Step a: By the definition of $S$, any $f \in S$ is everywhere greater than zero, and therefore $Q_{0}[f]$ holds.

Step b: Suppose $Q_{i}[f]$ holds for some $i$ and $f \in S$. Then by definition, $f(x)>i$ for all natural numbers $x$. Using this property, we can simpl ify the expression $r[f](x)$ :

$$
T[f](x)=\text { if } f(x+1)>0 \text { then } f(x+1)+1 \text { else } 8
$$

- $f(x+1)+1$.

Since $f(x+1)>i$, we have $f[f](x)>i+1$. Therefore $Q_{i+1}[f[f]]$ also holds.

Step c: Suppose that some total function $f \in S$ satisfies $Q_{i}[f]$ for all $i$. Then for any natural number $x, f(x)>i$ for $a l i$, and this is clearly a contradiction. Therefore any such $f$ also satisfies $Q[f]$ which is always "false".

This completes the induction step, and the method thus guarantees that $S$ does not contain any fixedpoint of P4.

Thus far we have introduced the new assertion induction method. As mentioned above, the two classical proof method8 can also be used to prove properties of the optimal $f$ ixedpoint. We show here an appropriately modified version of the structural induction method.

## The Structural induction M ethod

The structural induction method is intended to prove that a ixedpoint $f$ of a recursive program $P$ has some "pointwise" property $Q[f](x)$ for al $I x$ in the domain D. The main idea is to partition $D$ into subsets $S_{0}, S_{1}, \ldots$ such that

$$
D=\bigcup_{j=0}^{\infty} S_{j}
$$

and to prove that $Q[f](x)$ hold8 for al $I x \in S_{i}$ using induction over the index $i$. Thus, one ha8 to show' that for any $i$, if $Q[f] .(x)$ hold8 for al

> i-l
$x \in \mathbf{u s}$,
$\mathrm{j}=0$.
then $\mathbb{Q}[f](x)$ holds for all $x \in S_{i}$.
This implication is usually proved by freely replacing any occurrence of $f$ by $r[f]$ (since fis a fixedpoint) and applying the induction hypothesis to the resultant expression'. This method can also be used to prove properties of optimal $f$ ixedpoints, but one usually has to apply some additional specific reasoning techniques, such as equation solving or case analysis of possible valuer,

We illustrate this method with the following program P5 over the natural numbers:
P5: $F(x)<=$ if $x=0$ then 8 else $F(x-F(x))$.

We would like to prove that the optimal fixedpoint f of P5 satisfiess
$Q[f](x): f(x)=0$
for any natural number $\mathbf{x}$.

We partition the domain of natural number8 in the follouing way:

$$
S_{\theta}=\{0\} \quad S_{1}=\{1\} \quad S_{2}=\{2\} \ldots
$$

The fact that $Q(f)(\theta)$. hold 8 (i.e., $f(\theta)-\theta) i 8$ a direct consequence of the definition of P5.
i-1
Assume that we have already shown that $Q[f](x)$ holds for all $x \in U S_{j}$
je8
(i.e., for al l $0 \leq x \leq i-1)$; we now prove that $Q[f](x)$ holds for all $x \in S_{i}(1 . e .$, for $x-i)$. Since $f$ is a fixedpoint of $P 5$ and $i>8$, we have:

$$
f(i)=f(i-f(i)) .
$$

We use case analysis in order to find all the possible value8 of $f(i)$.
One possible value of $f(i)$ is clearly $u n d e f i n e d$. In order to check whether $f(i)$
has any possible defined value, assume that $f(i)=k$ for some natural number $k$. Substituting this value into the definition of $f(i)$, we get:

$$
k=f(i)=f(i-f(i))=f(i-k) .
$$

We consider two possible cases:
(a) If k-8, we obtain the roquirement

$$
\theta=f(i)
$$

and this value is clearly consistent with our assumption that $f(i)=k=0$. Thus zero is apossible value of $f(i)$.
(b) If $k>8$, we obtain the requirement that

$$
f(i-k)>8,
$$

but since $i>8$ and $k>8$, $i-k<i$, and this contradicts what we know (in the induction hypothesis) about the optimal f ixedpoint:

$$
f(x)=0 \text { for all } x, \theta \leq x \geq i
$$

Therefore $f(i)$ cannot have the value $k$ for any $k>8$.

We have thus shown'that the only two possible values of $f(i)$ are undefined and $B$. By the definition of the optimal fixedpoint, we can now deduce that $f(i)=0$. Since this holds for any natural number i , the optimal fixedpoint is everywhere defined as zero.

## VI. Conclusion

In this paper we have presented the optimal fixedpoint approach towards recursive programs. Whi le it is clearly appealing from a theoretical point of view, it has a drawback in practicc: it may be either impossible or extremely hard to find the optimal fixedpoint of some recursive programs. While we cannot develop perfect implementations, we can try (perhaps using heuristic techniques) to extract as much information from the program as possible. Such an implementation wil lyield the optimal fixedpoint for Certain classes Of recursive programs; it will compute some intermediate fxp-consistent fixedpoint for other classes; and in the worst case wi I l yield the least fixedpoint of the program (as computed by the classical stack implementation). By insisting on finding a more informative solution of a recursive program than the least $f$ ixedpoint, it is natural that the efficiency of
computation rules is reduced and the complexiity of proof techniques is increased.

The development of this neu approach is still undsruay, both in its theoretical and practical aspects.

## ***********************

Footnotes
(i) Al I functions in this program map natural numbers into natural numbers; thus, $x-1$ is defined to be 8 for $x-8$.
( i i ) The theorem is proved in Manna and Shamir [1975], Theorem 3.
(iii) For a more rigorous statement of this result and its proof see Theorem 5 in Manna and Shamir [1975].
