#### Abstract

:

This' paper considers the computation of matrix chain products of the form Mlx $M_{2} \times \ldots M_{n-1}$. If the matrices are of different dimensions, the order in which the product is computed affects the number of operations. An optimum drder is an order which minimizes the total number of operations. We present some theorems about an optimum order of computing the matrices. Based on these theorems, an $O(n \log n)$ algorithm for finding an optimum order is presented in part II.

This research was supported in part by National Science Foundation grant MCS-77-23738 and U.S. Army Research Office grant DAAG29-80-C-0029.

1. Introduction

Consider the evaluation of the product of $n-1$ matrices

$$
\begin{equation*}
\mathbf{M}=M_{1} \times M_{2} \times \cdot{ }^{* *} \mathbf{e} \times \mathbf{M}_{\mathbf{n - 1}} \tag{1}
\end{equation*}
$$

where $M_{i}$ is a $w_{i} \times w_{i+1}$ matrix, Since matrix multiplication satisfies the associative law, the final result $M$ in (1) is the same for all orders of multiplying the matrices. However, the order of multiplication greatly affects the total number of operations to evaluate $M$. The problem is to find an optimum order of multiplying the matrices such that the total number of operations is minimized. Here, we assume that the number of operations to multiply a $p \times q$ matrix by a $q \times r$ matrix is pqr.

In [1][7], a dynamic programming algorithm is used to find an optimum order. The algorithm needs $O\left(\mathbf{n}^{3}\right)$ time and $O\left(n^{2}\right)$ space. In [2], Chandra proposed a heuristic algorithm to find an order of computation which requires no more than $2 \mathrm{~T}_{0}$ operations where $\mathrm{T}_{\mathrm{o}}$ is the total number of operations to evaluate (1) in an optimum order. This heuristic algorithm needs only $O$ (n) time. Chin [3] proposed an improved heuristic algorithm to give an order of computation which requires no more than $1.25 \mathrm{~T}_{0}$, This improved heuristic algorithm also needs only $O(n)$ time.

In this paper we first transform the matrix chain product problem into a problem in graph theory - the problem of partitioning a convex polygon into non-intersecting triangles, see $[9][10][11][12]$, then we state several theorems about the optimum partitioning problem. Based on these theorems, an $O(n \log n)$ algorithm for finding an optimum partition is developed.
2. Partitioning a convex polygon

Given an n- sided convex polygon, such as the hexagon shownin Fig. 1 , the number of ways to partition the polygon into (n-2) triangles by non-intersecting diagonals is the Catalan numbers (see for example, Gould [8]). Thus, there are 2 ways to partition a convex quadrilateral, 5 ways to partition a convex pentagon, and 14 ways to partition a convex hexagon.

Let every vertex $V_{i}$ of the polygon have a positive weight $\underset{1}{w . .}$ We can define the cost of a given partition as follows: The cost of a triangle is the product of the weights of the three vertices, and the cost of partitioning a polygon is the sum of the costs of all its triangles. For example, the cost of the partition of the hexagon in Fig. $I$ is

$$
\begin{equation*}
w_{1} w_{2} w_{3}+w_{1} w_{3} w_{6}+w_{3} w_{4} w_{6}+w_{4} w_{5} w_{6} . \tag{2}
\end{equation*}
$$

Fig. 1

If wc crascthediagonal from $V_{3}$ to $V_{6}$ andreplace it by the diagonal from $\quad V_{1}$ to $V_{4}$, then the cost of the new partition will be

$$
\begin{equation*}
w_{1} w_{2} w_{3}{ }^{t} w_{1} w_{3} w_{4}+w_{1} w_{44} w_{6}{ }^{\mathrm{w}}{ }_{45} 5_{6}{ }^{w} . \tag{3}
\end{equation*}
$$

We will prove that an order of-multiplying (n- 1) matrices corresponds to a partition of a convex polygon with $n$ sides. The cost of the partition is the total number of operations needed in multiplying the matrices. For brevity, we shall use $n$-gon to mean a convex polygon with $n$ sides, and the partition of an $n$-gon to mean the partitioning of an n-gon into (n-2) non-intersecting triangles.

For any $n$-gon, one side of the $n$-gon will be considered to be its base, and will usually be drawn horizontally at the bottom such as the side $V_{1}-V_{6}$ in Fig. 1. This side will be called the base, all other sides are considered in a clockwise way. Thus, $V_{1}-V_{2}$ is the first side, $V_{2}-V_{3}$ the second side,. .., and $V_{5}-V_{6}$ the fifth side.

The first side represents the first matrix in the matrix chain and the base represents the final result $M$ in (1). The dimensions of a matrix are the two weights associated with the two end vertices of the side. Since the adjacent matrices are compatible, the dimensions $w_{1} \times w_{2}, w_{2} \times w_{3}$, $\ldots, w_{n-1} \times w_{n}$ can be written inside the vertices as $w_{1}{ }_{2}, \ldots, w_{n}$. The diagonals arc the partial products. A partition of ann-goncorresponds to an alphabetic tree of $n$-l leaves or the parenthesis problem of n-1 symbols (see, for example, Gardner [6]). It is easy to see the one-toone correspondence between the multiplication of n-l matrices to either
the alphabetic binary tree or the parenthesis problem of $n$ - ; symbols. Here, we establish the correspondence between the matrix-chain product and the partition of a convex polygon directly.

Lemma 1. Any order of multiplying n-l matrices corresponds to a partition of an n-gon.

Proof. We shall use induction on the number of matrices. For two matrices of dimensions $w_{1} X^{w_{2}}, w_{2} x_{3} w_{3}$ there is only one way of multi plication, this corresponds to a triangle where no further partition is required. The total number of operations in multiplication is $w_{1} w_{2} w_{3}$, the product of the three weights of the vertices. The resulting matrix has dimension $w_{1} X w_{3}$. For three matrices, the two orders of multiplication $\left(M_{1} \times M_{2}\right) \times M_{3}$ and $M_{1} \times\left(M_{2} \times M_{3}\right)$ correspond to the two ways of partitioning a 4-gon. Assume that this lemma is true for $k$ matrices where $k \leq n-2$, and we now consider n-l matrices. The n-gon is shown in Fig. 2.

Fig. 2

Let the order of multiplication be represented by

$$
\mathbf{M}=\left(M_{1} \times M_{2} \times \cdots \times M_{p 1}\right) \times\left(M_{p} \times \cdots \times M_{n 1}\right)
$$

i. e., the final matrix is obtained by multiplying a matrix of dimension ( $w_{1} \times w_{p}$ ) and a matrix of dimension ( $w_{p} \times w_{n}$ ). Then in the partition of the n-gon, we let the triangle with vertices $V_{1}$ and $V_{n}$ have the third vertex $V_{p}$. The polygon $V_{1}-V_{2}-\ldots-V_{P}$ is a convex polygon of $p$ sides with base $V_{1}-V_{P}$ and its partition corresponds to an order of multiplying matrices $M_{1}, \ldots, M_{p-1}$, giving a matrix of dimension $w_{1} \times w_{p}$. Similarly, the partition of the polygon $\mathrm{V}_{\mathrm{p}}-\mathrm{V}_{\mathrm{p}+1^{-}} \ldots \mathrm{V}_{\mathbf{n}}$ with base $\mathbf{V}_{\mathbf{P}}-\mathbf{V}_{\mathbf{n}}$ corresponds to an order of multiplying matrices $M_{P}, \ldots, M_{n} 1$, giving a matrix of dimension $w_{p} X_{n}$. Hence the triangle $V_{l} V_{p} V_{n}$ with base $V \mathbf{1 -} V_{n}$ represents the multiplication of the two partial products, giving the final matrix of dimension $w_{1} \times{ }_{\mathbf{n}}$.

Lemtna 2. The minimum number of operations to evaluate the following matrix chain products are identical,

$$
\begin{gathered}
M_{1} \times M_{2} \times \cdots \times M_{n-2} \times M_{n-1} \\
M_{n} \times M_{1} \times \cdots \times M_{n-3} \times M_{n-2} \\
\vdots \\
M_{2} \times M_{3} \times \cdots \times M_{n 1} \times M_{n}
\end{gathered}
$$

where M. has dimension $w_{i} \times{ }^{w_{i+1}}$ and $w_{n+1} \equiv w$, Note thati $n$ the first matrix chain, the resulting matrix is of dimension $w, b y w_{n}$, In the last matrix chain, the resulting matrix is of dimension $w_{2}$ by $w_{1}$. But in all the cases, the total number of operations in the optimum orders of multiplication is the same.

Proof. The cyclic permutations of the $n-1$ matrices all correspond to the same n-gon and thushave I hesame optimum partitions.
(This Lemma was obtained independently in [4] with a long proof, )

From now on, we shall concentrate only on the partitioning problem.

The diagonals inside the polygon are called arcs. Thus, one easily verifies inductively that every partition consists of n-2 triangles formed by $n-3$ arcs and $n$ sides.

In a partition of an non, the degree of a vertexis the number of arcs incident on the vertex plus two (since there are two sides incident on every vertex).

Lemma 3. In any partition of an $n$-gon, $n \geq 4$, there are at least two triangles, each having a vertex of degree two. (For example, in Fig. 1, the triangle $V_{1} V_{2} V_{3}$ has vertex $V_{2}$ with degree 2 and the triangle $V_{4} V_{5} V_{6}$ has vertex $V_{5}$ with degree 2.) (See also [5].)

Proof. In any partition of an n-gon, there are n- 2 non-intersecting triangles formed by $n-3$ arcs and $n$ sides. And for any $n \geq 4$, no triangle can be formed by 3 sides. Let $\mathbf{x}$ be the number of triangles with two sides and one arc, $y$ be the number of triangleswithoneside and two ares, and zo be the numbero ftriangles withthree ares.

Since an arc is'used in two triangles, we have

$$
\begin{equation*}
\mathbf{x} \mathbf{t} 2 \mathrm{y} \text { t } 3 \mathrm{z}=2(\mathrm{n}-3) . \tag{4}
\end{equation*}
$$

Since the polygon has $n$ sides, we have

$$
\begin{equation*}
2 x+y=n \tag{5}
\end{equation*}
$$

From (4) and (5), we get

$$
3 \mathbf{x}=3 z+6
$$

Since $\quad z \geq 0$, we have $x \geq 2$.

Lemma 4. Let $P$ and $P^{\prime}$ both be n-gons where the corresponding weights of the vertices satisfy $w_{i} \leqslant w_{i}^{\prime}$, then the cost of an optimum partition of $P$ is less than or equal to the cost of an optimum partition of $P^{\prime}$.

Proof. Omitted.

If we use $C\left(w_{1}, w_{2}, w_{3}, \ldots, w k\right)$ to mean the minimum cost of partitioning the k-gon with weights $w_{i}$ optimally, Lemma 4 can be stated as

$$
C\left(w_{1}, w_{2}, \ldots, w_{k}\right)<C\left(w_{1}^{\prime}, w_{2}^{\prime}, \ldots, w_{k}^{\prime}\right) \text { i f } w_{i} \leq w_{i}^{\prime}
$$

We say that two vertices arc connected in an optimum partition if the two vertices are connected by an arc or if the two vertices are adjacent to the same side.

In the rest of the paper, we shall use $V_{1}, V_{2}, \ldots, V_{n}$ to denote vertices which are ordcred according to their weights, i. e. $w_{1} \leq w_{2} \leq \cdot, \leq w_{n}$, To facilitate the presentation, we introduce a tie-breaking rule for vertices of equal weights,

If there are two or more vertices with weights equal to the smallest weight $w_{1}$, we can arbitrarily choose one of these vertices to be the vertex $V_{1}$. Once the vertex $V_{1}$ is chosen, further ties in equal weights are resolved by regarding the vertex which is closer to $\mathrm{V}_{1}$ in the clockwise direction to be of less weight. With this tie-breaking rule, we can unambiguously label the vertices $V_{1}, V_{2}, \ldots, V_{n}$ for each choice of $V_{1}$. A vertex $V_{i}$ is said to be
 $w_{i}=w_{3}$, and $i<j$. We say that $V_{i}$ is the smallest vertex in a subpolygon if it is smaller than any other vertices in the subpolygon.

After the vertices are labeled, we define an arc $V_{i}-V_{j}$ to be less than $\operatorname{another} \operatorname{arc} \mathbf{V}_{\mathbf{P}}-\mathbf{V}_{\mathbf{q}}$
if

$$
\min (i, j)<\min (p, q)
$$

or $\quad\left\{\begin{array}{l}\min (i, j)=\min (p, q) \\ \max (i, j)<\max (p, q) .\end{array}\right.$
(For example, the arc $\mathrm{V}_{3}-\mathrm{V}_{9}$ is less than the arc $\mathrm{V}_{4}-\mathrm{V}_{5}$.) Every partition of an n-gon has $n-3$ arcs which can be sorted from the smallest to the largest into an ordered sequence of arcs, i.e., each partition is associated with a unique ordered sequence of arcs. We define a partition $P$ to be lexicographically less than a partition $Q$ if the ordered sequence of arcs associated with $P$ is lexicographically less than that associated with $Q$.

When there is more than one optimum partition, we use the,
$\ell$-optimum partition (i. e., lexicographically-optirnum partition) to mean the lexicographically smallest optimum partition, and use an optimum partition to mean some partition of minimum cost.

We shall use $V_{a}, V_{b}, \ldots$ to denote vertices which are unordered in weights, and $T_{i j k}$ to denote the product of the weights of any three vertices $V_{i}, V_{j}$ and $V_{k}$.

Theorem 1. For every way of choosing $V_{1}, V_{2}, \ldots$ (as prescribed), there is always an optimum partition containing $V 1-V_{2}$ and $V_{1}-V_{3}$. (Here, $V_{1}-V_{2}$ and $V_{1}-V_{3}$ may be either arcs or sides.)

Proof: The proof is by induction. For the optimum partitions of a triangle and a 4-gon, the theorem is true. Assume that the theorem is true for all $k$-gons ( $3 \leq k \leq n-1$ ) and consider the optimum partitions of an n-gon,

From Lemma 3, in any optimum partition, we can find at least two vertices having degree two. Call these two vertices $V_{i}$ and $V_{j}$. We can divide this into two cases.
(i) One of the two vertices $\mathrm{V}_{\mathrm{i}}$ (or $\mathrm{V}_{\mathrm{j}}$ ) is not $\mathrm{V}_{1}, \mathrm{~V}_{2}$ or $\mathrm{V}_{3}$ in some optimum partition of the $n$-gon. In this case, we can remove the vertex $V_{i}$ with its two sides and obtain an (n-1)-gon. In this (n-1)-gon, $V_{1}, V_{2}, V_{3}$ are the three vertices with smallest weights. By the induction assumption, $V_{1}$ is connected to both $V_{2}$ and $V_{3}$ in an optimum partition.
(ii) Consider the complementary case of (i), in all the optimum partitions of the $n$-gon, all the vertices with degree two are from the set $\left\{\mathrm{V}_{1}, \mathrm{~V}_{2}, \mathrm{~V}_{3}\right\}$. (In this case, there will be at most three vertices with degree two in every optimum partition. ) We have the following three subcascs:
(a) $V_{i}=V_{2}$ and $V_{j}=V_{3}$ in some optimum partition of the n-gon, i.e., both $V_{2}$ and $V_{3}$ have degree two simultaneously, In this case, we first remove $\mathrm{V}_{2}$ with its two sides and form an ( $\mathrm{n}-1$ )-gon. By the induction assumption, $V 1, V_{3}$ must be connected in some optimum partition, If $\mathrm{V}_{1}-\mathrm{V}_{3}$ appears as an arc, it reduces to (i). So $V_{1}-V_{3}$ must appear as a side of the ( $n-1$ )-gon, and reattaching $V_{2}$ to the ( $\mathrm{n}-1$ )-gon shows that either $\mathrm{V}_{1}, \mathrm{~V}_{2}$ and $\mathrm{V}_{3}$ are mutually adjacent or $V_{1}-V_{3}$ is a side of the $n$-gon. In the former case, the proof is complete, so we assume that V1-V3 is a side of the n-gon. Similarly, we can remove $\mathrm{V}_{3}$ with its two sides and show that $\mathrm{V}_{1}, \mathrm{~V}_{2}$ are connected by a side of the $n$-gon.
(b) $V_{1}=V 1$ and $V_{j}=V_{2}$ in some optimum partition of the n-gon, i.e., $V 1$ and $V_{2}$ both have degree two simultaneously. In this case, we can first remove $V_{1}$ and form an (n-1)-gon where $V_{2}, V_{3}$, $\mathrm{V}_{4}$ are the three vertices with smallest weights. By the induction assumption, $V_{2}$ is connected to both $V_{3}$ and $V_{4}$ in an optimum partition. If $\mathrm{V}_{2}-\mathrm{V}_{3}$ or $\mathrm{V}_{2}-\mathrm{V}_{4}$ appears as an arc, it reduces to (i). Hence, $V_{2}-V_{3}$ and $V_{2}-V_{4}$ must both be sides of the $n$-gon. Similarly, we can remove $V_{2}$ with its two sides and form an (n-1)-gon where $V_{1}, V_{3}, V_{4}$ are the three vertices with smallest weights.

Again, Vl must be connected to $\mathrm{V}_{3}$ and $\mathrm{V}_{4}$ by sides of the n -gon. But for any $n$-gon with $n \geq 5$, it is impossible to have $V_{.3}$ and $V_{4}$ both adjacent to $V 1$ and $V_{2}$ at the same time, i.e., $V_{1}$ and $V_{2}$ cannot both have degree two in an optimum partition of any n-gon with $\mathbf{n} \geq 5$.
(c) $v_{i}=V_{1}, v_{j}=V_{3}$ in some optimum partition of the n-gon. By argument similar to (b), we can show that $\mathrm{V}_{2}$ must be adjacent to Vl and $\mathrm{V}_{3}$ in the n-gon. The situation is as shown in Fig. 3(a).

Then the partition in Fig. 3(b) is cheaper because

$$
\mathrm{T}_{123} \leqslant \mathrm{~T}_{12 \mathrm{q}}
$$

and $\mathrm{C}\left(\mathrm{w}_{1}, \mathrm{w}_{\mathrm{q}}, \underset{\mathbf{Y}}{\mathbf{w}}, \mathrm{w}_{\mathrm{t}}, \mathrm{w}_{\mathrm{x}}, \mathrm{w}_{\mathrm{p}}, \mathrm{w}_{3}\right) \leq \mathrm{C}\left(\mathrm{w}_{2}, \mathrm{w}_{\mathrm{q}}, \mathrm{w}_{\mathrm{y}}, \mathrm{w}_{\mathrm{t}}, \mathrm{w}_{\mathrm{x}}, \mathrm{w}_{\mathrm{p}}, \mathrm{w}_{3}\right)$
according to Lemma 4.

(a)

(b)

Fig. 3

Corollary 1. For every way of choosing $V 1, V_{2}, \ldots$ (as prescribed), the $\ell$-optimum partition always contains $V_{1}-V_{2}$ and $V_{1}-V_{3}$.

Proof: It follows from Theorem 1 and the definition of the $\ell$-optimum partition.

Once we know $V_{1}-V_{2}$ and $V 1-V_{3}$ always cxist in the $\ell$-optimum partition, we can use this fact recursively. Hence, in finding the $\ell$-optimum partition of a given polygon, we can decompose it into subpolygons by joining the smallest vertex with the second smallest and third smallest vertices repeatedly, until each of these subpolygons has the property that its smallest vertex is adjacent to both its second smallest and the third smallest vertices.

A polygon having Vl adjacent to $\mathrm{V}_{2}$ and $\mathrm{V}_{3}$ by sides will be called a basic polygon.

Theorem 2. A necessary but not sufficient condition for $V_{2}-V_{3}$ to exist in an optimum partition of a basic polygon is

$$
\frac{1}{\mathrm{w}_{1}}+\frac{1}{\mathrm{w}_{4}} \leq \frac{1}{\mathrm{w}_{2}}+\frac{1}{\mathrm{w}_{3}}
$$

Furthermore, if $V_{2}-V_{3}$ is not present in the $\ell$-optimum partition, then $V_{1}, V_{4}$ are always connected in the $\ell$-optimum partition.

Proof. If $\mathrm{V}_{2}, \mathrm{~V}_{3}$ are not connected in the $\ell$-optimum partition of a basic polygon, the degree of $V_{1}$ is greater than or equal to 3. Let $V_{p}$ be a vertex in the polygon and $\mathrm{V} 1, \mathrm{~V}_{\mathrm{p}}$ are connected in the $\ell$-optimum partition. $\mathrm{V}_{4}$ is either in the subpolygon containing $\mathrm{V} 1, \mathrm{~V}_{2}$ and $\mathrm{V}_{\mathrm{p}}$ or in the subpolygon containing $V 1, V_{3}$ and $\underset{P}{V}$. In either case, $V_{4}$ will be the third smallest vertex in the subpolygon. From Corollary 1, V1, $V_{4}$ are connected in the $\ell$-optimum partition of the subpolygon and it also follows that $\mathrm{V}_{1}, \mathrm{~V}_{4}$ are connected in the $\ell$-optimum partition of the basic polygon.

If $V_{2}, V_{3}$ are connected in an optimum partition, then we have an ( $\mathrm{n}-1$ )-gon where $\mathrm{V}_{2}$ is the smallest vertex and $\mathrm{V}_{4}$ is the third smallest vertex. By Theorem 1, there exists an optimum partition of the (n-1)-gon in which $V_{2}, V_{4}$ are connected. Thus by induction on $n$, we can assume that $V_{4}$ is adjacent to $V_{2}$ in the basic polygon as shown in Fig. 4(a).

Fig. 4

The cost of the partition in Fig. 4(a) is

$$
\begin{equation*}
\mathbf{T}_{123} \cdot \mathrm{C}\left(\mathrm{w}_{2}, \mathrm{w}_{4}, \ldots, \mathrm{w}_{\mathrm{t}}, \ldots, \mathrm{w}_{3}\right) \tag{7}
\end{equation*}
$$

And the cost of the partition in Fig. 4(b) is

$$
\begin{equation*}
\mathbf{T}_{124}+\mathrm{C}\left(\mathrm{w}_{1}, \mathrm{w}_{4}, \ldots, \mathrm{w}_{\mathrm{t}}, \ldots, \mathrm{w}_{3}\right) \tag{8}
\end{equation*}
$$

According to Lemma 4,

$$
\begin{equation*}
C\left(w_{1}, w_{4}, \infty, w_{t}, \ldots, w_{3}\right)<C\left(w_{2}, w_{4}, \ldots, w_{t}, \ldots, w_{3}\right) . \tag{9}
\end{equation*}
$$

Since the weights of the vertices between $V_{4}$ and $V_{3}$ in the clockwise direction are all greater than or equal to $w_{4}$, the difference between RHS and LHS of (9) is at least

$$
\mathbf{T}_{243}-\mathrm{T}_{143}
$$

. the necessary condition for (7) to be no greater than (8) is

$$
\mathrm{T}_{123}+\mathrm{T}_{243} \leq \mathrm{T}_{124}+\mathrm{T}_{\mathbf{1 3 4}}
$$

or

$$
-\frac{1}{w_{1}}+\frac{1}{w_{4}} \leq \frac{1}{w_{2}}+\frac{1}{w_{3}}
$$

Lemma 5. In an optimum partition of an n-gon, let $V_{x}, V_{y}, V_{z}$, and $V_{w}$ be four vertices of an inscribed quadrilateral $\left(V_{x}\right.$ and $V_{z}$ are not adjacent in the quadrilateral). A necessary condition for $\mathrm{V}_{\mathrm{x}}-\mathrm{V}_{\mathrm{Z}}$ to exist is

$$
\begin{equation*}
\frac{1}{w_{x}}+\frac{1}{w_{z}} \geq \frac{1}{w_{y}}+\frac{1}{w_{w}} \tag{10}
\end{equation*}
$$

Proof: The cost of partitioning the quadrilateral by the arc $V_{x}-V_{z}$ is

$$
\begin{equation*}
\mathbf{T}_{\mathbf{x y z}}+\mathrm{T}_{\mathbf{x z w}} \tag{11}
\end{equation*}
$$

and the cost of partitioning the quadrilateral by the arc $\mathbf{V}_{Y}-V_{W}$ is

$$
\begin{equation*}
\mathbf{T}_{\mathbf{x y w}}+\mathrm{T}_{\mathbf{y z w}} \tag{12}
\end{equation*}
$$

For optimality, we have (11) $\leq(12)$ which is (10).

Note that if strict inequality holds in (10), the necessary condition is also sufficient. If equality holds in (10), the condition is sufficient for $V_{x}-V_{z}$ to exist in the $\ell$-optimum partition provided $\min (x, z)<\min (y, w)$, This lemma is a generalization of Lemma 1 of Chin [3] where $V_{Y}$ is the vertex with the smallest weight and $\mathrm{V}_{\mathrm{x}}, \mathrm{V}_{\mathrm{w}}, \mathrm{Vz}$ are three consecutive vertices with $\mathrm{w}_{\mathrm{w}}$ greater than both $\underset{X}{w}$ and $w_{z}$.

A partition is called stable if every quadrilateral in the partition satisfies (10).

Corollary 2, An optimum partition is stable but a stable partition may not be optimum,

Proof. The fact that optimum partition has to be stable follows from Lemma 5 .
Figure 5 gives an example that a stable partition may not be optimum.

Fig. 5

In any partition of an n-gon, every arc dissects a unique quadri-
lateral. Let $V_{x}, V_{y}, V_{z}, V_{w}$ be the four vertices of an inscribed quadrilateral and $V_{x}-V_{z}$ be the arc which dissects the quadrilateral. We define $V_{x}-V_{z}^{\text {to }}$ be a vertical arc if (13) or (14) is satisfied.

$$
\left.\begin{array}{l}
\min \left(w_{x}, w_{7}\right)<\min _{7}\left(w_{y}, w_{w}\right) \\
\left.\min \left(w_{x}, w_{z}\right)=\min _{w^{\prime}}, w_{y}\right)  \tag{14}\\
\max \left(w_{x}, \underset{z}{w_{w}}\right) \leq \max \left(w_{Y}, w_{w}\right)
\end{array}\right\}
$$

We define $V_{x}-V_{z}$ to be a horizontal arc if (15) is satisfied

$$
\begin{align*}
& \min \left(w_{x}, w_{z}\right)>\min \left(w_{Y}, w_{w}\right) \\
& \max \left(w_{x}, w_{z}\right)<\max \left(w_{Y}, w_{w}\right) \tag{15}
\end{align*}
$$

For brevity, we shall use h-arcs and v-arcs to denote horizontal arcs and vertical arcs from now on.

## Corollary 3. All arcs in an optimum partition must becithervertical

 arcs or horizontal arcs.Proof: Let $V_{x}-V_{z}$ be an arc which is neither vertical nor horizontal.
There are'two cases:

Case 1. $\quad \min \left(w_{x}, w_{z}\right)=\min \left(w_{Y}, w_{w}\right)$
and $\quad \max \left(w_{x}, w_{z}\right)>\max \left(w_{Y}, w_{w}\right)$

Case 2. $\quad \min \left(w_{x}, w_{z}\right)>\min \left(\underset{Y}{w}, w_{w}\right)$
and $\quad \max \left(w_{x}, w_{z}\right) \geq \max \left(w_{Y}, w_{w}\right)$.

In both cases, the inequality (10) in Lemma 5 cannot be satisfied.

This implies that the partition is not stableandhenrecannofbeoplimum.

Theorem 3. Let $V_{x}$ and $V_{z}$ be two arbitrary vertices which arc nd adjacent in a polygon, and $V_{w}$ be the smallest vertex from $V_{x}$ to $V_{z}$ in the clockwise $\operatorname{manner}\left(\mathrm{V}_{\mathrm{w}} \neq \mathrm{V}_{\mathrm{x}}, \mathrm{V}_{\mathrm{w}} \neq \mathrm{V}_{\mathrm{z}}\right)$, and $\mathrm{V}_{\mathrm{Y}}$ be the smallest vertex from $\mathrm{V}_{\mathrm{z}}$ to $\mathrm{V}_{\mathrm{x}}$ in the clockwise manner $\left(\mathrm{V}_{\mathrm{Y}} \neq \mathrm{V}_{\mathrm{x}}, \mathrm{V}_{\mathrm{Y}}^{\neq \mathrm{V}_{\mathrm{Z}}}\right)$. This is shown in Fig. 6 where without loss of generality, we assume that $\mathrm{V}_{\mathrm{x}}<\mathrm{V}_{\mathrm{z}}$ and $\mathrm{V}_{\mathrm{y}}<\mathrm{V}_{\mathrm{w}}$. A necessary condition for $V_{X}-V_{z}$ to exist as an $h$-arc in the $\ell$-optimum partition is that

$$
w_{y}<w_{x} \leq w_{z}<w_{w} .
$$

(Note that the necessary condition still holds when the positions of $\mathbf{V}_{\mathbf{Y}}$ and $\mathbf{V}_{\mathbf{W}}$ are interchanged.)

Fig. 6

Proof, The proof is by contradiction. If $w_{x} \leq \underset{Y}{w}, w_{x}$ must be equal to the smallest weight $w_{1}$ and $V_{x}-V_{z}$ can never satisfy (15). Hence, in order that $V_{X}-V_{z}$ exists as an $h$-arc in the $\ell$-optimum partition, we must
 the clockwise manner and $\underset{X}{ }<V_{W}$, we must have $V_{Y}=v_{1}$.

Assume for the moment that $V=V_{x}<V z$. From Corollary 1, both $\mathrm{VI}-\mathrm{V}_{2}$ and $\mathrm{V}_{1}-\mathrm{V}_{3}$ exist in the $\ell$-optimum partition, and the two arcs would divide the polygon into subpolygons. If $V_{x}$ and $V_{z}$ are in different subpolygons, then they cannot be connected in the $\ell$-optimum partition. Without loss of generality, we can assume that the polygon is a basic polygon. In this basic polygon, either $\mathrm{V}_{2}-\mathrm{V}_{3}$ or $\mathrm{V}_{1}-\mathrm{V}_{4}$ exists in the $\ell$-optimum partition (Theorem 2).

If $\mathrm{V}_{2}, \mathrm{~V}_{3}$ are connected, then $\mathrm{V}_{\mathrm{x}}$ and $\mathrm{V}_{\mathrm{z}}$ are both in a smaller polygon in which we can treat $V_{2}$ as the smallest vertex and repeat the argument. If $\mathrm{V}_{1}, \mathrm{~V}_{4}$ are connected, the basic polygon is again divided into two subpolygons and $\mathrm{V}_{\mathrm{x}}$ and $\mathrm{V}_{\mathrm{z}}$ both have to be in one of the subpolygons and the subpolygon has at most $n-1$ sides, (Otherwise $V_{X}-V_{z}$ can never exist in the $\ell$-optimum partition. ) The successive reduction in the size of the polygon will either make the connection $X_{X}-V_{z}$ impossible, or force $V_{x}$ and $V_{z}$ to become the second smallest and the third smallest vertices in a basic subpolygon. Let $\mathrm{V}_{\mathrm{m}}$ be the smallest vertex in this basic subpolygon. In order that $V_{x}-V_{z}$ appear as an h-arc, we must have $w_{x}>w_{m}$. From Theorem 2, the necessary condition for $V_{x}-V_{z}$ (i.e. $V_{2}-V_{3}$ ) to exist in an optimum partition of the subpolygon is

Since $w_{x}>w_{m}$, the inequality is valid only if $w_{z}<w_{w}$
Corollary 4. A weaker necessary condition for $V_{x}-V_{z}$ to exist as an h-arc
in the $\boldsymbol{\ell}$-optimum partition is that

$$
\mathrm{V}_{\mathrm{y}}<\mathrm{V}_{\mathrm{x}}<\mathrm{V}_{\mathrm{z}}<\mathrm{V}
$$

Proof. This follows from Theorem 3.

We call any arc which satisfies this weaker necessary condition a potential h-arc. Let $P$ be the set of potential $h$-arcs in the $n$-gon and $H$ be the set of $h$-arcs in the $\ell$-optimum partition, we have $P \supseteq H$ where the inclusion could be proper.

Corollary 5. Let $V_{w}$ be the largest vertex in the polygon and $V_{X}$ and $V_{Z}$ be its two neighboring vertices. If there exists a vertex $V={ }_{Y}$ such that $V_{y}<V_{x}$ and $V_{Y}<V_{z}$, then $V_{x}-V_{z}$ is a potential h-arc.

Proof. This follows directly from Corollary 4 where there is only one vertex between $V_{X}$ and $V_{*}$.

Two arcs are called compatible if both arcs can exist simultaneously in a partition. Assume that all weights of the vertices are distinct, then there are (n-1)! distinct permutations of the weights around an n-gon, For example, the weights $10,11,25,40,12$ in Fig. $5(a)$ correspond to the permutation $\quad w_{1}, w_{2}, w_{4}, w_{5}, w_{3}\left(\right.$ where $\left.w_{1}<w_{2}<w_{3}<w_{4}<w_{5}\right)$. There are infinitely many values of the weights which correspond to the same permutation. For example, 1, $16,34,77,29$ also corresponds to $w_{1}, w_{2}, w_{4}, w_{5}, w_{3}$ but its optimum partition is different from that of $10,11,25,40,12$. However, all the potential $h$-arcs in all the $n$-gons with the same permutation of weights are compatible, We state this remarkable fact as Theorem 4.

Theorem 4, All potential $h$-arcs are compatible.
 vertices described in Theorem 3. Hence, we have $\underset{\mathbf{Y}}{\mathbf{V}}<\underset{\mathbf{x}}{\mathbf{V}}<\mathrm{V}_{\mathrm{Z}}<\mathbf{V}_{\mathbf{W}}$
and $V_{x}-V_{z}$ is a potential $h-a r c$. Let $V_{P}-V_{q}$ be a potential $h$-arc which is not compatible to $V_{x}-V_{z}$, as shown in Fig. 7. Without loss of generality, we can assume $V_{P}<V_{q}$. (The proof for the case $V_{q}<V_{r}$ is similar to that which follows.)

Fig. 7

Since $V_{W}$ is the smallest vertex between $V_{X}$ and $V_{Z}$ in the clockwise manner, we have $v_{z}<\mathrm{V}_{\mathrm{w}}<\mathrm{V}_{\mathrm{q}}$. Hence, we have either $\mathrm{V}_{\mathrm{V}}<\mathrm{V}_{\mathrm{p}}<\mathrm{V}_{\mathrm{Z}}<\mathrm{V}_{\mathrm{q}}$ or $\mathrm{V}_{\mathrm{Y}}<\mathrm{V}_{\mathrm{z}}<\mathrm{V}_{\mathrm{p}}<\mathrm{V}_{\mathrm{q}}$. Both cases violate Corollary 4 and $\mathrm{V}_{\mathrm{P}}-\mathrm{V}_{\mathrm{q}}$ cannot be a potential h-arc.

Note that the potential $h-\operatorname{arc} V_{x}-V_{z}$ always dissects the $n$-gone into two subpolygons and one of these subpolygons has the property that all its vertices except $V_{x}$ and $V_{z}$ have weights no smaller than $\max \left(w_{x} X^{v}\right)$. Wc shall call this subpolygon the upper subpolygon of $\mathrm{V}_{\mathrm{x}}-\mathrm{V}_{\mathrm{z}}$. For example, the subpolygon $v_{x} \cdots-v_{w} \cdots-v_{q}-\cdots-v_{z}$ in Fig. 7 is the upper subpolygon of ${ }_{x}-V_{z}$.

Using Corollary 4 and Theorem 4, we can generate all the potential
h-arcs of a polygon.

Let $V_{x}-V_{Z}$ be the arc defined in Corollary 5 , i.e. $V_{1}<V_{x}<V_{z}<V_{W}$. The arc $V_{x}-V_{z}$ is a potential $h$-arc compatible to all other potential $h$-arcs in the n-gon. Furthermore, there is no other potential h-arc in its upper subpolygon. Now consider the ( $n-1$ )-gon obtained by cutting out $V_{w}$. In this (n-1)gon, let $V_{W}$, be the largest vertex and $V_{x}$, and $V_{z}$, be the two neighbors of $\mathbf{V}_{\mathbf{W}}$, where $\mathrm{V}_{\mathbf{l}}<\mathrm{V}_{\mathrm{x}^{\prime}}<\mathrm{V}_{\mathrm{z}^{\prime}}<\mathrm{V}_{.0}$. Then $\mathrm{V}_{*},-\mathrm{V}_{c}$, is again a potential h-arc compatible to all other potential $h$-arcs in the $n$-gon and there is no other potential h-arc in its upper subpolygon which has not been generated. This is true even if $V_{w}$ is in the upper subpolygon of $V_{x},-V_{z}$, If we repeat the process of cutting out the largest vertex, we get a set $P$ of arcs, all arcs satisfy Corollary 4. The h-arcs of the $\ell$-optimum partition must be a subset of these arcs.

The process of cutting out the largest vertex can be made into an algorithm which is $O(n)$. We shall call this algorithm the one-sweep algorithm. The output of the one-sweep algorithm is a set $S$ of $n-3$ arcs. $S$ is empty initially.

## The one - sweep algorithm:

Starting from the smallest vertex, say $V_{1}$, we travel in the clockwise direction around the polygon and push the weights of the vertices successively onto the stack as follows ( $w_{1}$ will be at the bottom of the stack).
(a) Let $\mathrm{V}_{\mathrm{t}}$ be the top element on the stack, $\mathrm{V}_{\mathrm{t} 1}$ be the element immediately below $\mathrm{V}_{t}$, and $\mathrm{V}_{\mathrm{c}}$ be the element to be pushed onto the stack.

If there are two or more vertices on the stack and $w_{t}>w_{C}$, add $V_{t l}{ }^{-V_{c}}$ to $S$, pop $V_{t}$ off the stack; if there is only one vertex on the stack or $w_{t} \leq w_{c}$, push $w_{c}$ onto the stack. Repeat this step until the $n^{\text {th }}$ vertex has been pushed onto the stack.
(b) If there are more than three vertices on the stack, add $\mathrm{V}_{\mathrm{t}} \mathrm{l}^{-} \mathrm{V}_{\mathrm{C}}$ to $S$, pop $V_{t}$ off the stack and repeat this step, else stop.

Since we do not check for the existence of a smallest vertex whose weight is strictly no larger than those of the two neighbors of the largest vertex, i. e. the existence of the vertex $V_{Y}$ in Corollary 4, not all the $n-3$ arcs generated by the algorithm are potential $h$-arcs. However, it is not difficult to verify that the one-sweep algorithm always generates a set $\mathbf{S}$ of $\mathbf{n - 3}$ arcs which contains the set $P$ of all potential $h$-arcs which contains the set $H$ of all $h$-arcs in the $\ell$-optimum partition of the $n$-gon, i.e.,

$$
S \supseteq P \supseteq H
$$

where each inclusion could be proper. For example, if the weights of the vertices around the $n$-gon in the clockwise direction are $w_{1} w_{2}, \ldots, w_{n}$ where $w_{1} \leq w_{2} \leq \cdots \leq w_{n}$, none of the arcs in the $n$-gon can satisfy Corollary 4 and hence there are no potential $h$-arcs in the n-gon. The onesweep algorithm would still generate $n-3$ arcs for then-gon but none of the arcs generated is a potential $h$-arc.
3. Conclusion

In this paper, we have presented several theorems on the Polygon Partitioning Problem. Some of these theorems are characterizations of the optimum partitions of any n-sided convex polygon, while the others apply to the unique lexicographically smallest optimum partition. Based on these theorems, an $O(n)$ algorithm for finding a near-optimum partition can be developed [12]. The cost of the partition produced by the heuristic algorithm never exceeds 1 , 155 Copt, where Copt is the optimum cost of partitioning the polygon. An $O(n \log n)$ algorithm for finding the unique lexicographically smallest optimum partition will be presented in part II.
4. Acknowledgment

The authors would like to thank the referees for their helpful comments in revising the manuscript.

#### Abstract

:

This paper considers the computation of matrix chain products of the form $M 1 \times M_{2} \times \ldots \times M_{n-1}$. If the matrices are of different dimensions, the order in which the matrices are computed affects the number of operations. An optimum order is an order which minimizes the total number of operations. Some theorems about an optimum order of computing the matrices have been presented in part $I$. Based on those theorems, an $O(n \log n)$ algorithm for finding the optimum order is presented here.

[^0]
## 1. Introduction

In Part I of this paper, we have transformed the matrix chain product problem into the optimum partitioning problem and have stated several theorems about the optimum partitions of an $n$-sided convex polygon. Based on these theorems, we now present algorithms for finding the unique $\ell$-optimum (lexicographically smallest optimum) partition.

Using the same notation as in Part I of this paper, we can assume that we have uniquely labelled all vertices of the n-gon. A partition is called a fan if it consists of only $v$-arcs joining the smallest vertex to all other vertices in the polygon. We shall denote the fan of a polygon $V_{1}-V_{b}-V_{m}-V_{n}$ by $\operatorname{Fan}\left(w l \mid w_{b}, w_{c}, \ldots, w\right)_{i}$ The smallest vertex $V 1$ is called the center of the fan.

We define a vertex as a local maximum vertex if it is larger than its two neighbors and define a vertex as a local minimum vertex if it smaller than its two neighbors. A polygon is called a monotone polygon if there exists only one local maximum and one local minimum vertex. We shall first give an $O(n)$ algorithm for finding the $\ell$-optimum partition of a monotone polygon and then give an $O(n \log n)$ algorithm for finding the $\ell$-optimum partition of a general convex polygon.

## 2. Monotone Basic Polvgon

In this section, let us consider the optimum partition of a monotone polygon, i. e. a polygon with only one local minimum vertex and one local maximum ve $r$ tex. It follows from Corollary 1 of Part I that we can
consider a monotone basic polygon only. The understanding of this special case is necessary in finding the optimum partition of a general convex polygon.

Consider a monotone basic n-gon $\mathrm{Vl}-\mathrm{V}_{2}-\mathrm{V}_{\mathrm{c}}-\ldots-\mathrm{V}_{3}$, the fan of the polygon is denoted by

$$
\operatorname{Fan}\left(w_{1} \mid w_{2}, w_{c}, \ldots, w_{3}\right)
$$

where the smallest vertex $V_{1}$ is the center of the fan.
The definition of a fan can also be applied to subpolygons as well. For example, if $\mathrm{V}_{2}, \mathrm{~V}_{3}$ are connected in the basic $n$-gon and $\mathrm{V}_{2}$ becomes the smallest vertex in the ( $n$ - 1 )-sided subpolygon, the partition formed by connecting $\mathrm{V}_{2}$ to all vertices in the ( $\mathrm{n}-1$ )-gon is denoted by

$$
\operatorname{Fan}\left(w_{2} \mid w_{c}, \ldots, w_{3}\right) .
$$

Lemma 1. If none of the potential $h$-arcs appears in the $\ell$-optimum partition of the $n$-gon, the $\ell$-optimum partition must be the fan of the $n$-gon.

Proof. From Theorem 3 of Part I, we know that any arc which exists as an $h$-arc in the $\ell$-optimum partition must be a potential $h$-arc. Hence, if the $\ell$-optimum partition does not contain any potential $h-a r c$, the $\ell$-optimum partition must be made up of v-arcs only. Hence, we have to show that among all partitions which are made up of $v$-arcs only, the fan is (i) the lexicographically smallest and (ii) one of the cheapest partitions in the n-gon.
(i) Since the fan consists of only $v$-arcs joining $V_{1}$ to all other vertices in the $n$-gon, it is by definition the lexicographically smallest- partition.
(ii) Suppose the $\ell$-optimum partition contains $v$-arcs only but is not the fan. There must exist three vertices $V_{i}, V_{k}, V_{j}$ such that the triangles
$\mathrm{V}_{1} \mathrm{~V}_{\mathrm{i}} \mathrm{V}_{\mathrm{j}}$ and $\mathrm{V}_{\mathrm{i}} \mathrm{V}_{\mathrm{j}} \mathrm{V}_{\mathrm{k}}$ are present in the $\ell$-optimum partition. Since, $\mathrm{V}_{\mathrm{i}}-\mathrm{V}_{\mathrm{j}}$ is a v-arc (by assumption) and $V_{1}$ is the smallest vertex in the n-gon, we have $w l=\min \left(w_{i}, w_{j}\right)$ and $\max \left(w_{i}, w_{j}\right) \leq w_{k}$. If we replace the v-arc $V_{i}-V_{j} b y$ the $v$-arc $V_{l}-V_{k}$, we can get a partition whose cost is less than or equal to that of the $\ell$-optimum partition but is lexcographically smaller than the $\ell$-optimum partition, and results in a contradiction.

Let $V_{i}-V_{j i}$ and $V_{P}-V_{q}$ be two potential h-arcs of any n-gon. We say that $V_{1} .-V_{j}$. is above $\underset{P}{V}-V_{q}\left(\right.$ and $V_{p}-V_{q} \underset{i s}{ }$ below $V_{i}-V_{j}$ ) if the upper subpolygon of $V_{P}-V_{q}$ contains the upper subpolygon of $\underset{i}{ } V_{j}-V_{j}$

Let $P$ be the set of all potential $h$-arcs in monotone basic n-gon. $P$ can have at most (n-3) arcs.

Lemma 2. For any two arcs in $P$, say $V_{i}-V_{j}$ and $V_{p}-V_{q}$, we must have either $V_{i}-V_{j}$ above $V_{P}-V_{q}$ or $V_{p}-V_{q}$ above $V_{i}-V_{j}$.

Proof. By contradiction. Let $V_{i}-V_{j}$ and $V_{P}-V_{q}$ be two arcs in $P$ which do not satisfy this lemma. Then the intersection of the upper subpolygons of $V_{i}-V_{j}$ and $V_{P}-V_{q}$ must either be empty or consists of part of each upper subpolygon only.

Since the vertices other than $V_{i}, V_{j}$ in the upper subpolygon of $V_{i}-V_{j}$ must have weights larger than $\max \left(w_{i}, w_{j}\right)$, the local maximum vertex of the monotone basic polygon must be present in the upper subpolygon of $V_{i}-V_{j}$. Similarly, the local maximum vertex of the monotone basic polygon
 sections of the upper subpolygons of $\underset{1}{V} .-V_{j}$. and $V_{P}-V_{q}$ cannot be empty.

From Theorem 4 of Part $I$, we know that $V_{i}-V_{J}$ and $\underset{P}{V}-V_{q}$ cannot cross each other and hence the intersection of their upper subpolygons cannot consist of part of each upper subpolygons only.

We can actually show this ordering of potential h-arcs pictorially by drawing a monotone basic polygon in such a way that the local maximum vertex is always at the top and the local minimum vertex is at the bottom. Then a potential $h$-arc $\mathbf{V}_{1} \cdot-V_{\mathbf{J}}$ is physically above another potential $h$-arc $\mathrm{V}_{\mathrm{p}}-\mathrm{V}_{\mathrm{q}}$ if the upper subpolygon of $\mathbf{V}_{\mathbf{P}}-\mathrm{V}_{\mathrm{cl}}$ contains the upper subpolygon of $V_{i}-V_{\mathbf{j}}$. From the definition of the upper subpolygon, we can see that

Consider the monotone basic n-gon which is shown symbolically in Figure 1. $V_{n}$ is the local maximum vertex and $V_{i}-V_{j i}, V_{p}-V_{q}$ are potential h-arcs of the monotone basic n-gon. The subpolygon $\underset{P}{V}-\ldots-V_{i}-V_{j i}-\ldots-V_{q}$ which is formed by two potential $h$-arcs $V_{P}-V_{q}$ and $V_{i}-V_{j}$ and the sides of the $n$-gon from $V_{P}$ to $V_{i}$ and from $V_{j}$ to $V_{q}$ in the clockwise direction is said to be bounded above by the potential $h$-arc $V_{i}-V_{j}$ and bounded below by the potential h-arc $\underset{\mathrm{P}}{\mathrm{V}}-\mathrm{V}_{\mathrm{q}}$,

Figure 1

Lemma 3. Any subpolygon which is bounded by two potential $h$-arcs of the monotone basic $n$-gon is itself a monotone polygon.

Proof, Consider the subpolygon $\underset{\mathbf{P}}{\mathbf{V}} \ldots \mathrm{V}_{\mathrm{i}}-\mathrm{V}_{\mathrm{Ji}}-\ldots-\mathrm{V}_{\mathrm{q}}$ in Figure 1. Without loss of generality, we can assume $\mathrm{V}_{\mathrm{i}}<\mathrm{V}$. and $\mathrm{V}_{\mathrm{p}}<\underset{\mathrm{q}}{\mathrm{V}}$. Since $V_{n}$ is the only local maximum vertex in the monotone basic $n$-gone, we must have $\quad \mathbf{V I}<\underset{\mathbf{P}}{\mathbf{V}}<\ldots<\mathrm{V}_{\mathbf{r}}<\mathbf{V}_{\mathbf{n}}$ and $\mathbf{V}_{\mathbf{n}}>\mathrm{V}_{\mathrm{j}}>\ldots>\mathrm{V}_{\mathrm{q}}>\mathrm{V}_{\mathrm{l}}$. Hence, $\mathbf{V}_{\mathbf{P}}$ is the unique local minimum vertex and $V_{j}$ is the unique local maximum vertex in the subpolygon $P$ $V-\ldots-V_{i}-V_{i}-\ldots-V_{q}$. By definition, $V_{P}-\cdots-V_{i}-V_{j}-\cdots-V_{q}$ is a monotone polygon.

Lemma 4. Any potential h-arc of a subpolygon bounded above and below by two potential $h$-arcs of the monotone basic n-gon is also a potential h-arc of the monotone basic n-gon.

Proof. Consider the subpolygon $\underset{P}{V}-\ldots-V_{i}-V_{j i}-\ldots-V_{q}$ in Figure 1. Let $V_{x}-V_{z}$ be a potential $h$-arc in this subpolygon and $V_{w}$ is the smallest vertex between $V_{x}$ and $V_{z}$ in the clockwise direction around the subpolygon. Without loss of generality, we can assume $\mathrm{V}_{\mathbf{i}}<\mathrm{V}_{\mathrm{j}}, \mathrm{V}_{\mathrm{p}}<\mathrm{V}_{\mathrm{q}}$ and $\mathrm{V}_{\mathrm{x}}<\mathrm{V}_{\mathrm{z}}$. Since $V_{x}$ is in the upper subpolygon of the potential $h$-arc $V_{P}-V_{q}$, we have ${ }^{w_{1}}<\mathrm{w}_{\mathrm{p}} \leq \mathrm{w}_{\mathrm{q}}<\mathrm{w}_{\mathrm{x}} \leq \mathrm{w}_{\mathrm{z}}$. Since $\mathrm{V}_{\mathrm{j}}<$ any vertex in the upper subpolygon of $V_{i}-V_{\dot{J}}$ and $V_{w}<V_{1}<V_{j}, V_{w}$ is the smallest vertex between $V_{x}$ and $V_{z}$ in clockwise direction around the monotone basic n-gon. Hence, we have $\mathrm{w}_{1}<\mathrm{w}_{\mathrm{x}} \leq \mathrm{w}_{\mathrm{z}}<\mathrm{w}_{\mathrm{w}}$ and $\mathrm{V}_{\mathrm{x}}-\mathrm{V}_{\mathrm{z}}$ is a potential h-arc of the monotone basic n-gon.

We can now summarize what we have discussed. If there is no h-arc in the l-optimum partition of monotone basic n-gon, the $\ell$-optimum partition must be a fan. Otherwise, the h-arcs in the $\ell$-optimum partition are all layered, one above another. If we consider the local maximum vertex $V_{n}$ and the local minimum vertex $V_{1}$ as two degenerated $h$-arcs, then the $\ell$-optimum partition of a monotone basic $n$-gon will contain one or more monotone subpolygons, each bounded above and below by two h-arcs and the $\ell$-optimum partition of each of these monotone subpolygons is a fan.

Then, in finding the $\ell$-optimum partition of a monotone basic polygon, we have only to consider those partitions which contain one or more subpolygons bounded above and below by potential $h$-arcs and each of these subpolygons is partitioned by a fan. Since there are at most (n-3) nondegenerated potential h-arcs in monotone basic n-gon, there will be at most $2^{\text {n-3 }}$ such partitions and we can divide all these partitions into (n-2) classes by the number of non-degenerated potential $h$-arcs a partit ion contains. These classes are denoted by $\mathrm{H}_{0}, \mathrm{H}_{1}, \ldots, \mathrm{H}_{\mathrm{n} 3}$ where the subscript indicates the number of non-degenerated potential h-arcs in each partition of that class.

There is no potential $h$-arc in the partitions in the class $H_{0}$. Hence the class consists of only one partition, namely the fan

$$
\operatorname{Fan}\left(w_{1} \mid w_{2}, \ldots, w_{3}\right)
$$

In the class $H_{1}$, each partition has one non-degenerated potential $h$-arc. Once the potential $h$-arc is known, the rest of the arcs must all be vertical arcs forming two fans, one in each subpolygon.

Two typical partitions in Hl of a monotone basic polygon are shown in Fig. 2. In Fig. 2a, there is one non-degenerated potential h-arc, $V_{c}-V_{i}\left(V_{c}<V_{i}\right)$. The upper subpolygon is a fan

$$
\operatorname{Fan}\left(w_{c} \mid w_{d}, \ldots, w_{i}\right)
$$

and the lower subpolygon is a fan

$$
\operatorname{Fan}\left(w_{1} \mid w_{2}, w_{c}, w_{i}, w_{3}\right) .
$$

(a)

(b)

Fig. 2. Two typical partitions in $\mathrm{H}_{1}$ of a monoton 10-gon.

In Fig. 2 b , there is one potential h -arc, $\mathrm{V}_{2}-\mathrm{V}_{3}$, and the upper subpolygon is a fan

$$
\operatorname{Fan}\left(w_{2} \mid w_{c}, \ldots, w_{3}\right)
$$

and the lower subpolygon is a degenerated fan, a triangle.
Assume that $V_{2}-V_{3}$ is the only $h$-arc, then the cost is (see Fig. 2b)

$$
\begin{gather*}
{ }_{w_{1}} w_{2} w_{3}+w_{2}\left(w_{c} w_{d}+w_{d} w_{e}+w_{e} w_{f}+w_{f}{\underset{g}{g}}^{w}+w_{g} \underline{w}_{h}+w_{h} w_{i}+w_{i} w_{3}\right) \\
=T_{123} t w_{2}\left(w_{c}: w_{3}\right) \tag{1}
\end{gather*}
$$

where $w_{c}: w_{3}$ is the shorthand notation of the sum of adjacent products from $\mathrm{w}_{\mathrm{c}}$ to $\mathrm{w}_{3}$ in the clockwise direction.

Note that the cost of $\mathrm{H}_{0}$ of the polygon shown in Fig. 2 is

$$
\begin{gather*}
\operatorname{Fan}\left(w_{1} \mid w_{2}, \ldots, w_{3}\right) \\
=w_{1}\left(w_{2}: w_{3}\right) \tag{2}
\end{gather*}
$$

The condition of (1) to be less than (2) is

$$
\frac{w_{2} \cdot\left(w_{c}: w_{3}\right)}{\left({\underset{w}{2}}_{2}: w_{3}\right)-w_{2} \cdot w_{3}}<w_{1}
$$

Similarly, the condition for the partition in Fig. 2a to be less $\operatorname{than} \mathrm{H}_{0}$ is

$$
\begin{equation*}
\frac{\cdot\left(w_{d}: w_{i}\right)}{\left(w_{1}: w_{i}\right)-w_{0} \cdot \mathbb{1}_{1}}<w_{1} \tag{3}
\end{equation*}
$$

We say that a partition is said to be $\ell$-optimal among the partitions in a certain class (or several classes) if it is the lexicographically smallest partition among all the partitions with minimum cost in that class (or several classes). Hence, the $I$-optimum partition is $I$-optimal among all partitions in the classes $H_{0}, H_{1}, \ldots$, and $H_{n 3}$.

Now, assume that the $P$-optimal partition among all the partitions in $H_{1}, H_{2}, \ldots, H_{n-3}$ contains only one potential h-arc $\underset{i}{V_{k}}-V_{k}$ only, as shown in Fig. 3. (Note that $V_{1 i}-V_{k}$ will exist in this partition as an h-arc. ) This partition will be the $\ell$-optimum partition of the monotone basic $n$-gon if it costs less than that of the fan in $H_{0}$, The condition that the partition with $\mathrm{V}_{\mathrm{i}}-\mathrm{V}_{\mathrm{k}}$ as the single $h$-arc costs less than $\mathrm{H}_{0}$ is

$$
\frac{\left.w_{i} \cdot w_{k}\right)}{\left(w_{i}: w_{k}\right)-w_{i} \cdot w_{k}}<w_{1} \quad \text { if } w_{\cdot} \leq w_{k}
$$

or

Fig, 3. A monotone polygon with a single h-arc.

$$
\frac{w_{k} \cdot\left(w_{1}: w_{g}\right)}{\left(w_{i}: w_{k}\right)-w_{i} \cdot w_{k}}<w_{1} \quad \text { if } \quad w_{k}<w_{i}
$$

Combining the two inequalities above, we have

$$
\begin{equation*}
\frac{C\left(w_{i}, \cdots, w_{k}\right)}{\left(w_{i}-w_{k}\right)-w_{i} \cdot w_{k}}<w_{1} \tag{4}
\end{equation*}
$$

where $C\left(w_{i}, \ldots, w_{k}\right)$ denotes the cost of the optimum partition of the subpolygon ${ }_{1} w \cdot{ }_{j} \ldots \ldots \cdot{ }_{g}-w_{k}$ and is equal to the cost of the fan in this case.

An $h$-arc $V_{i}-V_{k}$ which divides a polygon into two subpolygons is called a positive arc with respect to the polygon if (4) is satisfied, i. e., the partition with the arc as the only $h$-arc and a fan in each of the two subpolygins costs less than the fan in the same polygon. Otherwise, it is called a negative arc with respect to the polygon.

When an n-gon is divided into subpolygons, an $h$-arc is defined as Positive in a subpolygon if the cost of partition of the subpolygon with the $h$-arc as the only $h$-arc is less than the fan in the subpolygon.

Let us consider a partition with two hares as shown in Fig. 4, and assume that this partition is $\ell$-optimal among all partitions in the $\operatorname{classes} H_{2}, H_{3}, \cdots H_{n-3}$.

Fig. 4. A monotone 8-gon with two h-arcs.

If $\mathrm{V}_{\mathrm{i}}-\mathrm{V}_{\mathrm{k}}$ is positive with respect to the subpolygon
$V_{1}-V_{i}-V_{p}-V_{q}-V_{k}$, then the condition analogous to (4) is

$$
\begin{equation*}
\frac{C\left(w_{i}, w_{p}, w_{q}, w_{k}\right)}{\left\{\left(w_{i}: w_{k}\right)-\left[\left(w_{p}: w_{q}\right)-w_{P} \cdot w_{q}\right]\right\}-w_{i} \cdot w_{k}}<w_{1} \tag{Fa}
\end{equation*}
$$

If $V_{i}-V_{k}$ is positive with respect to the whole polygon $\mathrm{V}_{1}-\mathrm{V}_{\mathrm{i}}-\ldots-\mathrm{V}_{\mathrm{n}}-\ldots-\mathrm{V}_{\mathrm{k}}$, then the condition is

$$
\begin{equation*}
\frac{C\left(w_{i},{\underset{p}{p}}_{\mathrm{r}^{\prime}}^{W_{n}^{\prime}}{ }^{w_{s}}, w_{q}, w, w_{k}\right)}{\left(w_{i}: w_{k}\right)-w_{i} \cdot w_{k}}<w_{l} \tag{5b}
\end{equation*}
$$

Note that (5b) implies (5a).

The condition for the $\operatorname{arc} V_{P}-V_{q}$ to be positive with respect to the subpolygon $V_{i}-V_{p}-V_{r} \quad-V_{n} \quad-V_{s} \quad-V_{q} \underset{k}{ } \quad$ is

$$
\begin{equation*}
\frac{C\left(w_{\mathbf{p}}, w_{\mathbf{r}}, w_{\mathbf{n}}, w_{\mathbf{s}}, w_{q}\right)}{\left(\mathrm{w}_{\mathrm{p}}: \mathrm{w}_{\mathrm{q}}\right)-\mathbf{w}_{\mathrm{p}} \cdot \mathrm{w}_{\mathrm{q}}}<\min \left(\mathrm{w}_{\mathrm{i}}, w_{\mathrm{k}}\right) . \tag{6a}
\end{equation*}
$$

If the arc $V_{P}-V_{q}$ is positive with respect to the whole polygon $V_{1}-V_{i}-V_{\mathbf{p}}^{-V} \underset{\mathbf{r}}{-\mathbf{V}} \underset{\mathbf{n}}{-\mathbf{V}}-\underset{\mathrm{s}}{ }-\mathrm{V}_{\mathrm{q}}-\mathrm{V}_{\mathrm{k}}$, it must satisfy (6b).

$$
\begin{equation*}
\frac{C\left(w_{p}, w_{r}, w_{n}, w_{s}, w_{q}\right)}{\left(w_{p}: w_{q}\right)-w_{p} \cdot w_{q}}<w_{1} \tag{6b}
\end{equation*}
$$

Since $w_{1}<\min \left(w_{1}, w k\right)$, condition (6b) implies (6a).
Here, the presence of $V_{i}-V_{k}$ will divide the original polygon into two subpolygons where $V_{p}-V_{q}$ appears in the upper subpolygon. If $V_{p}-V_{q}$ is a positive arc with respect to the original polygon, then $\mathrm{V}_{\mathbf{P}}-\mathrm{V}_{\mathrm{q}}$ is certainly positive in the upper subpolygon. But if $\underset{\mathbf{P}}{\mathbf{V}}-\mathrm{V}_{\mathrm{q}}$ is positive in the subpolygon, the arc $V_{P}-V_{q}$ may become negative if $V_{i}-V_{k}$ is removed, i, e. $V_{p}-V_{q}$ becomes negative with respect to the original polygon.

Similarly, if the arc $V_{i}-V_{k}$ is positive with respect to a subpolygon, the arc $V_{i} .-V_{k}$ may become negative if the arc $\underset{P}{V} \underset{\sim}{V}$ is removed,

The preceding discussions can be summarized as Theorem 1.

Theorem 1. If an $h$-arc is positive with respect to a polygon then the arc is positive with respect to any subpolygon containing that arc. If an h-arc is positive with respect to a subpolygon, it may or may not be positive with respect to a larger polygon which contains the subpolygon.

There are two intuitive approaches to the $\ell$-optimum partition of a monotone basic polygon. The first approach is to put in the potential h-arcs one by one. Each additional potential h-arc will improve the cost until the correct number of $h$-arcs is reached. Any further increase in the number of $h$-arcs will increase the cost. To introduce an $h$-arc into the polygon, we can test each potential $h$-arc (at most $n-3$ ) to see if it is positive with respect to the whole polygon. If yes, that positive arc must exist in the $P$-optimum partition, and the polygon will be divided into two subpolygons, each being a monotone polygon. We can repeat the whole process of testing positiveness of the $h$-arcs, The trouble is that all these arcs may be negative individually with respect to the whole polygon and yet $\mathrm{H}_{0}$ may not-be the optimum. For example, two $\operatorname{arcs} V_{i}-V_{j}$ and $V_{P}-V_{q}$ may be negative individually with respect to the
 same time may cost less than $H_{0}$ as shown in Fig. 5a. This shows that we cannot guarantee an optimum partition simply because no more potential $h$-arcs can be added one at a time.

The second approach is to put all the potential $h$-arcs in first and then take out the potential h-arcs one-by-one, where each deletion
will decrease the cost until the correct number of h-arcs is reached. Any further deletions will increasethe cost. Unfortunate3 $y$, even if all h-arcs are positive with respect to their subpolygon, the partition may not bc optimum. In Fig. 5b, each h-arc is positive with respect to its local subpolygon but the partition is not optimum. (Note that positiveness of an h-arc in a quadrilateral is the same as stability, But the idea of stability applied to vertical arcs as well.) This means that we cannot guarantee an optimum partition simply because no $h$-arc can be deleted one at a time.

Fig. 5. Counter examples for the intuitive approaches.

Let us outline the idea of an $O(n)$ algorithm for finding the $\ell$-optimum partition of a monotone basic polygon. First, we get all the potential $h$-arcs by the one-sweep algorithm. Then, we start from the highest potential $h$-arc and process each potential $h$-arc from the highest to the lowe st. For each potential $h$-arc, we try to get the $\ell$-optimum partition of the upper subpolygon of that arc (i. e. the $\ell$-optimum partition of the subpolygon bounded below by that $h$-arc). The $\ell$-optimum partition in the subpolygon is obtained by comparing the cost of the B-optimal partition among the partitions of the upper subpolygon which contain one or more potential $h$-arcs with that of the fan in the upper subpolygon.

If we try all possible combinations of the potential $h$-arcs as candidates for the $\ell$-optimal partitions, we need $O\left(n^{3}\right)$ operations to find the $\ell$-optimum partition. Fortunately, there are some dependencerelationships among these potential $h$-arcs. Hence, certain subsets of the potential $h$-arcs will either all exist or all disappear in the $I$ optimum partition of the monotone polygon. We shall be dealing with potential h-arcs most of the time, so we shall use "arcs" instead of potential h-arcs for brevity.

Consider the monotone basic polygon shown symbolically in Fig. 6. There are three potential $h$-arcs, denoted by $h_{k}, h_{j}$, and $h_{i}$. $\mathbf{V}_{n}$ is the local maximum vertex and $V_{1}$ is the local minimum vertex. Without loss of generality, we can assume $w_{a} \leq \mathbf{w}^{\prime}$ for $a=i, j$ and $k$. Since we shall deal with subpolygons bounded by two potential h-arcs, let ususe $h_{n}$ for $V_{n}$ and $h l$ for $V l$ (i. e. we consider these vertices as
degenerated arcs). From Lemmas 1 and 3 , the $\ell$-optimum partitions of the subpolygons bounded by two potential $h$-arcs (i.c. the white area of the polygon in Fig. 6) are all fans.

Assume (i) $h_{k}$ is positive in the subpolygon bounded by $h_{n}$ and $h_{j}$ but $h_{k}$ is negative in the subpolygon bounded by $h_{n}$ and $h_{i}$,
(ii) $h_{j}$ is positive in the subpolygon bounded by $h_{k}$ and $h_{i}$ but $h_{j}$ is negative in the subpolygon bounded by $h_{k}$ and $h l$, and
(iii) $h_{i}$ is positive in the, subpolygon bounded by ${ }_{J}$. and $h_{1}$ only. Then either the three $\operatorname{arcs} h_{k}, h_{\boldsymbol{J}} h_{i}$ all exist or no h-arcs exists in the optimum partition.

This shows that the existence of an $h$-arc depends on the existence of another h-arc.

We shall use the notations
$C\binom{h_{j}}{h_{i}}$ to denote the cost of the $\ell$-optimum partition of the subpolygon bounded above by $h_{j}$ and bounded below by $h_{i}$, and
$H_{0}\binom{h_{j}}{h_{i}}$ to denote the cost of the fan in the subpolygon bounded above by $h_{j}$ and bounded below by $h_{1}$.

Fig. 6. An octagon with three potential $h$-arcs.

In Fig. 6, the condition for $h k$ to be positive with respect to the whole polygon is (compare (Ea))

$$
\begin{equation*}
\frac{C\binom{h_{n}}{h_{k}}}{\left(w_{k}: w_{k}^{\prime}\right)-w_{k} \cdot w_{k}^{\prime}}<w_{1} \tag{7}
\end{equation*}
$$

The LHS of (7) is denoted by

$$
s\binom{h_{n}}{h_{k}}
$$

and is called the supporting weight of $h_{k}$ with $h_{n}$ as the ceiling (the definition of ceiling will be given formally later). Note that the LHS of ('7) depends only on the weights of vertices in the upper subpolygon of $h_{k}$.

In terms of the supporting weights, we can write the three conditions (i), (ii) and (iii) as follows:

$$
\begin{equation*}
w_{i}<S\binom{h_{\mathbf{n}}}{h_{k}}<w_{j} \tag{i}
\end{equation*}
$$

(ii)

$$
\begin{gathered}
w_{1}<s\binom{h_{k}}{h_{j}}<w_{i} \\
s\binom{h_{j}}{h_{k}}<w_{1} .
\end{gathered}
$$

An arc $h_{j}$ is a son of $t$ earc $h_{i}\left(\right.$ or $h_{i}$ is the father of $\left.h_{j}\right)$ if the following conditions are satisfied:
(i) $h_{j}$ is above $h_{1}$ (the son is above the father)
(ii) In any subpolygon containing $h_{i}$ and $h$., the arc $h_{y}$. will exist in the $\boldsymbol{\ell}$-optimum partition of the subpolygon if and only if $h_{\mathbf{c}_{1}}$ exists in the $\ell$-optimum partition.
(iii) $h_{i}$ is the highest arc that satisfies (i) and (ii). It is easy to see that every arc can have at most one father but an arc can have many sons. Also the ancestor-descendant relationship is a transitive relationship. If an arc exists in the $\ell$-optimum partition, all its descendants will also exist.

An arc $h_{k}$ is a ceiling of an arc $h_{i}$ if the following conditions are satisfied:
(i) $h_{k}$ is above $h_{i}$
(ii) $h_{k}$ is not a descendant of $h_{i}$
(iii) $h_{k}$ is the lowest arc which satisfies (i) and (ii).

Fig. 7. A subpolygon of the octagon shown in Fig. 6 (The shaded areas are optimally partitioned and the blank areas are partitioned by a fan. The $h$-arcs in the shaded area are all descendants of $h_{j}$.)

The cost of partition of Fig, Fa is

$$
C\binom{h_{k}}{h_{j}}+H_{0}\binom{h_{j}}{h_{i}}
$$

where the cost of partition in Fig. Tb is

$$
\mathbf{H}_{0}\binom{h_{k}}{h_{i}}
$$

The condition for the partition in Fig. Fa to be cheaper than that in Fig. Tb is (similar to (fa))

$$
\mathbf{S}\binom{h_{k}}{h_{j}}<w_{i}
$$

In order to give an intuitive meaning of the supporting weight $S\binom{h_{k}}{h_{j}}$, let us regard $h_{k}$ and $h_{j}$ in Fig. 7 as fixed while the position of $h_{1}$. can be moved up or down by increasing or decreasing the values of $w_{1}$ and $\mathbf{w}_{\mathbf{i}}{ }^{\prime}$.
 costs less than or equal to the partition in Fig. 7 b . If the position of $\mathrm{h}_{\mathrm{i}}$ moves down gradually from $h_{j}$, there will be a position for which the cost of the partition in Fig. $7 a$ is equal to the cost of the partition in Fig. $7 b$. We can consider this position as aictitious arc $f_{j}$, i. e.

$$
\begin{equation*}
C\binom{h_{k}}{h_{j}}+H_{0}\binom{h_{j}}{f_{j}}=H_{0}\binom{h_{k}}{f_{j}} \tag{8}
\end{equation*}
$$

the $\ell$-optimum partition of the subpolygon bounded by $h_{k}$ and $h_{i}$ becomes a fan. The arc $f_{j}$ is called the floor of ${ }^{h}{ }_{j}$ Note that the minimum of the two weights associated with $\underset{\mathfrak{J}}{f}$. is the supporting weight of $h_{\mathfrak{y}}$.

We now give two examples to illustrate the concepts, notations and the algorithms. Then a formal description of the algorithm will be given.

Consider a monotone basic polygon with five Potential h-arcs, $h_{6}, h_{5}, \ldots, h_{2}$ where $h_{6}$ is the highest arc as shown symbolically in Fig. 8. Let $w_{i} \leqslant w_{1}^{\prime}$ for $i=a, b,$. . , e. The maximum vertex, which lies above $h_{6}$, has the weight $w_{f}$ and the minimum vertex, which lies below $h 2$, has the weight $w_{1}$. We can regard $w_{f}\left(\right.$ and $\left.w_{l}\right)$ as a degenerated arc and use $h_{7}$ to represent $\mathbf{w}_{\mathbf{f}}$ ( ${ }^{\text {and } h_{1} \text { to repre- }}$ $\operatorname{sent} \quad w_{1}$ ).

Fig. 8 . A12-gon with 5 h-arcs,

Example 1
Let us write down the comparisons made in the algorithms.
First, we compare

$$
H_{0}\binom{h_{7}}{h_{6}}+H_{0}\binom{h_{6}}{f_{6}}=H_{0}\binom{h_{7}}{f_{6}}
$$

Fig. 9. Illustrations for Example 1.
qa. To find $f_{6}$.

In the equation, $f_{6}$ is the only unknown. In computation, we do not use the equation but use the supporting weight of $h_{6}$ instead ( $h_{7}$ is the ceiling of $h_{6}$ ). If the $h$-arc $h_{5}$ is below or coincides with $f_{6}$, which means that $h_{6}$ is negative with respect to the smallest subpolygon, $h_{6}$ should be deleted and never appear in the $\ell$-optimum partition, For simplicity, we shall assume all arcs and floors have distinct positions in the example.

Let us assume that $f_{6}$ is below $h_{5}$, or symbolically we write

$$
h_{5} / f_{6} .
$$

Fig. Pb. • The posit ion of $f_{6}$.

Then we do the next comparison.
$H_{0}\binom{h_{6}}{h_{5}}+H_{0}\binom{h_{5}}{f_{5}}=H_{0}\binom{h_{6}}{f_{5}}$

Fig. 9 c . To find $\mathrm{f}_{5}$.

Assume that $f_{6} / f_{5}$, ie. $h_{6}$ is a son of $h_{5}$, and $h_{4} / f_{5}$, the next comparison is
$H_{0}\binom{h_{7}}{h_{6}}+H_{0}\binom{h_{6}}{h_{5}}+H_{0}\binom{h_{5}}{f_{65}}=H_{0}\binom{h_{7}}{f_{65}}$.

Fig. Yd. Condense $h_{6}$ to $h_{5}$ and find $f_{65}$.

Note that $f_{65}$ is in a sense the combined floor of $h_{6}$ and. $h_{5}$ and $h_{7}$ becomes the ceiling of $h_{5}$. The equation can also be written as
$C\binom{h_{7}}{h_{5}}+H_{0}\binom{h_{5}}{f_{65}}=H_{0}\binom{h_{7}}{f_{65}}$
If $h_{4} / f_{65}$, the next comparison will be
$H_{0}\binom{h_{5}}{h_{4}}+H_{0}\binom{h_{4}}{f_{4}}=H_{0}\binom{h_{5}}{f_{4}}$

Fig. Me. To find f ${ }_{4}$.

Assume that $f_{65} / f_{4}$, i.e. $h_{5}$ is a son of $h_{4}$, and $h_{3} / f_{4}$, we have $C\binom{h_{7}}{h_{4}}+H_{0}\binom{h_{4}}{f_{654}}=H_{0}\binom{h_{7}}{f_{654}}$

Fig., 9f. To find $f_{654}$.
with $h_{7}$ as the ceiling of $h_{4}$, Moving to $h_{3}$, we compare

$$
\mathrm{H}_{0}\binom{\mathrm{~h}_{4}}{\mathrm{~h}_{3}}+\mathrm{H}_{0}\binom{\mathrm{~h}_{3}}{\mathrm{f}_{3}}=\mathrm{H}_{0}\binom{\mathrm{~h}_{4}}{\mathrm{f}_{3}}
$$

Fig. mg. To find $f_{3}$.

Assume that $f_{654} / f_{3}$, ie. $h_{4}$ is a son of $h_{3}$ and $h_{2} / f_{3}$, we compare $C\binom{h_{7}}{h_{3}}+H_{0}\binom{h_{3}}{f_{6543}}=H_{0}\binom{h_{7}}{f_{6543}}$

Fig. 9 h. To find $f_{6543}$.
with $h_{7}$ as the ceiling of $h_{3}$. Moving to $h_{2}$, we compare $\mathrm{H}_{0}\binom{\mathrm{~h}_{3}}{\mathrm{~h}_{2}}+\mathrm{H}_{0}\binom{\mathrm{~h}_{2}}{\mathrm{f}_{2}}=\mathrm{H}_{0}\binom{\mathrm{~h}_{3}}{\mathrm{f}_{2}}$

Fig. 9 i. To find $f_{2}$.

Assume that $f_{6543} / f_{2}$, ie. $h_{3}$ is a son of $h_{2}$, and $h_{1} / f_{2}$, we have

$$
C\binom{h_{7}}{h_{2}}+H_{0}\binom{h_{2}}{f_{65432}}=H_{0}\binom{h_{7}}{f_{65432}}
$$

Fig. oj. To find $f_{65432}$.
and $h$ is the ceiling of $h_{2}$. if

$$
S\binom{h_{7}}{h_{2}}<w_{1}
$$

the partition consisting of

$$
C\binom{h_{7}}{h_{2}}+H_{0}\binom{h_{2}}{h_{1}}
$$

is the $\ell$-optimum partition.

Fig. Mk. The $\ell$-optimum partition.

If $S\binom{h_{7}}{h_{2}} \geq w_{1}$, then $H_{0}\binom{h_{7}}{h_{1}}$ will he the $\ell$-optimum partition.

Exam le 2. The successive comparisons are

$$
H_{0}\binom{h_{7}}{h_{6}}+H_{0}\binom{h_{6}}{f_{6}}=H_{0}\binom{h_{7}}{f_{6}}
$$

Fig. 10. Illustrations for Example 2. 10a. To find $f_{6}$.

Assume that $h_{5} / f_{6}$, we compare

$$
H_{0}\binom{h_{6}}{h_{5}}+H_{0}\binom{h_{5}}{f_{5}}=H_{0}\binom{h_{6}}{f_{5}}
$$

Fig. 10b. To find $f_{5}$

Assume that $f_{5} / f_{6}$, i. e. $h_{6}$ becomes the ceiling of $h_{5}$, and $h_{4} / f_{5}$, we compare
$H_{0}\binom{h_{5}}{h_{4}}+H_{0}\binom{h_{4}}{f_{4}}=H_{0}\binom{h_{5}}{f_{4}}$

Fig. 10c. To find $f_{4}$

Assuming that $f_{4} / f_{5}$, i.e. $h_{5}$ becomes the ceiling of $h_{4}$, and $h_{3} / f_{4}$, we compare
$H_{0}\binom{h_{4}}{h_{3}}+H_{0}\binom{h_{3}}{f_{3}}=H_{0}\binom{h_{4}}{f_{3}}$

Fig. 10d. To find $f_{3}$.

Assume that $f_{3} / f_{4}$ and $f_{3} / h_{2}$, then arc $h_{3}$ should be deleted. Next, we assume that $f_{4} / h_{2}$, then arc $h_{4}$ should also be deleted, Suppose $h_{2} / f_{5}$, we shall then compare
$H_{0}\binom{h_{5}}{h_{2}}+H_{0}\binom{h_{2}}{f_{2}}=H_{0}\binom{h_{5}}{f_{2}}$

Fig. 10e. To find $f_{2}$.

Assume $f_{5} / f_{2}$, i. e. $h_{5}$ is a son of $h_{2}$ and $h l / f_{2}$, we then determine ${ }^{f} 52$,
$C\binom{h_{6}}{h_{2}}+H_{0}\binom{h_{2}}{f_{52}}=H_{0}\binom{h_{6}}{f_{52}}$

Fig. 10 . To find $f_{52}$.

Assume $f_{6} / f_{52}$, i. e. $h_{6}$ is anon Of $h_{2}$, and $h_{1} / f_{52}$, our next comprison is

$$
C\binom{h_{7}}{h_{2}}+H_{0}\binom{h_{2}}{f_{652}}=H_{0}\binom{h_{7}}{f_{652}}
$$

Fig. log. To find $f_{652}$.
and $h_{7}$ becomes the ceiling of $h_{2}$.
Assume $h_{1} / f_{652}$, the the partition $C\binom{h_{7}}{h_{2}}$ t $H_{0}\binom{h_{2}}{h_{1}}$ is the € -optimum partition.

Fig. 10 h . The $\ell$-optimum partition.

Had we assumed $f_{52} / f_{6}$ and $f_{52} / h_{1}$ then both $h_{5}$ and $h_{2}$ should also be removed and we are left with

$$
\mathrm{f}_{6} \text { against } \mathrm{h}_{1} .
$$

If $h_{1} / f_{6}$, then we have the $\ell$-optimum partition

$$
H_{0}\binom{h_{7}}{h_{6}}+H_{0}\binom{h_{6}}{h_{1}}
$$

From the above two examples, we can see that $h_{k}$ is the ceiling of $h_{i}$. if $h_{k}$ is the lowest arc above $h_{i}$ such that the supporting weight of $h_{k}$ is smaller than or equal to that of $h_{i}$.

Let us outline the algorithm for finding the $\ell$-optimum partition of a monotone basic polygon.

1. Get all the potential $h$-arcs of the polygon by the one-sweep algorithm. (All the $h$-arcs form a list with the arc $V_{b}-V_{b}$, at the bottom.)
2. Process the potential $h-\operatorname{arcs}$ one by one, from the top to the bottom.
(We try to find the $\ell$-optimum partition of the subpolygon bounded below by the arc being processed, )
$2 a$. Let $h_{R}$ be the arc currently being examined, $h_{C}$ be the arc immediately above $h_{R}$, and $h_{N}$ be the arc immediately below $h_{R}$ in the list. If $h_{R}$ is negative with respect to the subpolygon bounded above by $h_{C}$ and below by $h_{N}$, delete $h_{R}$, otherwise go to Step 2c.
$2 b$. Once $h_{R}$ and its descendants are deleted, we backtrack to $h_{C}$ and compare the cost of the partition with $h_{C}$ and its descendants against the cost of the fan in the subpolygon bounded above by the ceiling of $h_{C}$ and below by $h_{N}$. If the fan is $\ell$-optimum in the subpolygon, we will delete $h_{C}$ and repeat this step until no further deletion is possible. Then we move to examine $h_{N}$. (The actual comparisons are done in terms of the supporting weights.)

2c. Mere, $h_{R}$ is positive in the smallest subpolygon bounded by potential $h$-arcs. We will backtrack to condense all its descendants to $h_{R}$ as follows. Let $h_{C}^{\prime}$ be the ceiling of $h_{C}$. If
$S\binom{h_{C}}{h_{R}}<S\left(\begin{array}{l}h^{\prime} \\ h_{C} \\ h_{C}\end{array}\right), h_{C}$ becomes a son of $h_{R}$. We will combine $h_{C}$ as well as all its descendants to $h_{R}$ and recalculate the combined supporting weight $S\binom{h^{\prime}}{h_{R}}$. Replace $h_{C}$ by $h_{C}^{\prime}$ and compare the cost of the partition with $h_{R}$ and its descendants against that of the fan in the subpolygon bounded above by the new $h_{C}$, i. e. $h_{C}^{\prime}$, and below by $h_{N}$. If the fan is $\ell$-optimum in the subpolygon, we delete $h_{R}$ as well as its descendants, and go to Step $2 b$ to see if we can delete more arcs. Otherwise, we repeat this step to see if we can condense more arcs.
2d. Now we have $S\binom{h_{C}}{h_{R}} \geq S\binom{h^{\prime} C}{h_{C}}$, the supporting weight of $h_{C}$. The arc $h_{C}$ is the ceiling of $h_{R}$ and $S\binom{h_{C}}{h_{R}}$ is the supporting weight of $h_{R}$. We move and process $h_{N}$.

Before a formal description of the algorithm is given, a procedure to process the list of potential $h$-arcs in a monotone polygon is presented.

## Procedure MONO-PAKTITION (L)

Input: consists of a list of potential h-arcs, passed to the procedure via the argument $L$. Let $h_{1}$ be the lowest arc in $L$, the one immediately above $h_{1}$ be $h_{2}$, and $h_{p+1}$ be the highest arc in $L$. (Note that $h_{1}$ and $h_{p+1}$ are degenerated arcs with the minimum vertex and the maximum vertex of the polygon. )
out put: consists of all the potential $h$-arcs that exist in the P-optimum partition of the polygon.

Step 0 $\quad h_{C}:=\mathbf{h t l}_{\mathbf{p}}$;
$h_{R}:=h_{p}$;
$h_{\mathrm{N}}:=\mathbf{h}_{\mathbf{p - 1}}$;

MIN-WEIGHT : = minimum of the two vertices of $h_{N}$;
Comment: $h_{R}$ is the arc to be processed and $h C$ is the ceiling of the subpolygon. $h_{N}$ is the arc immediately below $h_{R}$ in $L$.

Step 1 Calculate $S\binom{h_{C}}{h_{R}}$;

If $S\binom{h^{h}}{h_{R}} \geq$ MIN-WEIGHT
then go to Step 2
else go to Step 3 .

Step 2 While ( $\mathrm{h}_{\mathrm{R}} \neq \mathrm{h}_{\mathrm{p}+1}$ ) And (the supporting weight of $h_{R} \geq$ MIN-WEIGHT) Do

## Begin

Remove $h_{R}$ and all its descendants from $L$;
$h_{R}:=h_{C}$;
$h_{C}:=$ the ceiling of the new $h_{R}$

## End;

Go to Step 4.

Step 3 If ( $h_{C} \neq \mathbf{h}_{\mathbf{t}}$ ) ${ }_{1}$ and (the supporting weight of $h_{R}<$ the supporting weight of $h_{C}$ )
then

## Begin

Condense $h_{C}$ and all its descendants into $h_{R}$;
$h_{C}:=$ the ceiling of $h_{C}$;
go to Step 1;
End
else.

## Begin

Record $S\binom{h_{C}}{h_{R}}$ as the supporting weight of $h_{R}$ and $h_{C}$ as
the ceiling of $h_{R}$;
go to Step 4;
End.
step 4 If $\mathrm{h}_{\mathrm{N}} \neq \mathrm{h}_{1}$
then
Begin

$$
h_{C}:=h_{R} \text {; }
$$

$h_{R}:=h_{N}$;
$h_{N}$ : = the arc immediately below the new $h_{R}$;
MIN-WEIGHT : = minimum of the two vertices of the new $h_{N}$;
go to Step 1;
End
else. go to Step 5 ;
step 5 Exit procedure and return $L$ to caller.
Now we can give the algorithm for finding the $\ell$-optimum parti-
tion of a monotone basic polygon.

## Algorithm I

In put consists of $n$ positive integers, which are the weights of the $n$ vertices of the monotone $n$-gon. $W[1]$ is the weight of the minimum vertex and $W[i+1]$ is the neighbor of $W[i]$ of the n-gon going in the clockwise direction. Let the weight of the maximum vertex be $W[t]$.
out put consists of a list of potential $h$-arcs which will exist. in the l-optimum partition of the $n$-gon, the partitions in the subpolygons bounded by every two consecutive arcs in the list are fans.

Step 0 For_ i : = 2 step 1 until $\mathbf{N}$ do

$$
C P[i]:=\sum_{j=1}^{l-l} \mathbf{W}[\mathbf{j}] \cdot W[j+1]:
$$

$C P[1]:=\mathbf{0}$;
Comment: The sum of adjacent products $W[i]: W[j]$ can be obtained from $C P[j]-C P[i]$ for $1 \leq i<j \leq N$ and hence we can calculate the supporting weights easily.
step 1 Apply the one - sweep algorithrn to obtain a list of arcs.
Let this list be $L$.

Comment: $L$ contains ( $n-3$ ) arcs which includes all potential
$h$-arcs in the monotone $n$-gon, and these arcs are layered, one above another.

Step 2 From L, remove those arcs which are not potential h-arcs;

If $L$ is empty
then go to Step 6
else go to Step 3.

Step 3 Let the lowest arc in $L$ be $h_{2}$, the one immediately above $h_{2}$ be $h_{3}$, and so on:

Let the highest arc in $L$, be $h_{p}$;
Insert $h_{1}$ with weight $w[1]$ below $h_{2}$;
Insert $h_{p+1}$ with weight $\mathbf{W}[t]$ above $\mathbf{h}_{\mathbf{P}}$.
Combnent: $\mathbf{h}_{p+1}$ is the ceiling of $\mathbf{h}_{\mathbf{p}}$.

Step 4 MONO- PARTITION (L);
Comment: when returned from MONO- PARTI'TION, L will contain all the ceiling arcs with their descendants in the d-optimum partition.

Step 5 Remove $h_{1}$ and $h_{p+1}$ from $L$;

Step 6 Output $L$ and stop.

This algorithm has been implemented in Pascal and the listing of the computer program is given in Appendix $I$.

Lemma 5. Any arc which is deleted from the arc-list $L$ in Step 2 of the procedure MONO-PARTITION cannot be present in the $\ell$-optimum partition of the polygon.

Proof. There are two cases in which an arc is deleted from L:
(1) Its ancestors are deleted. It follows from the definition of the ancestor -descendant relationship that it cannot be present in the $\ell$-optimum partition of the polygon.
(2) It is the $h_{R}$ which satisfies the logical condition of Step 2 of the procedure. Hence, in the subpolygon bounded below by $h_{N}$ and above by $h_{C}$, the partition with $h_{R}$ and its descendants costs more than or equal to that of the fan. Hence, the partition with $h_{R}$ and its descendants is not $\ell$-optimum in the subpolygon and $h_{R}$ as well as its descendants should not appear in the $\ell$-optimum partition of the whole polygon.

Lemma 6. After an arc $h_{i}$ has been processed, the subpolygon between $h_{1}$ and its ceiling is optimally partitioned.

Proof. The h-arcs remaining in the partition of the subpolygon are all descendants of $h_{1}$. By definition of the ancestor-descendant relationship, the partition of the subpolygon is optimum.

Lemma 7. Let $V_{t}$ be the maximum vertex, and $h_{k}, h_{k l}, \ldots, h_{j+1}$ be a set of $h$-arcs in the partition such that
and

$$
\begin{aligned}
& h_{k} \text { is the ceiling of } h_{k-l} \\
& h_{j t l} \text { is the ceiling of } h_{J} \text {, }
\end{aligned}
$$

then the supporting weights of these $h$-arcs satisfy

$$
\begin{equation*}
S\binom{h_{t}}{h_{k}} \leq S\binom{h_{k}}{h_{k-1}} \leq \cdots \leq s\binom{h_{j}+1}{h_{j}} \tag{9}
\end{equation*}
$$

Proof. Assume that one of the inequalities is not satisfied, say

$$
S\left(\begin{array}{l}
h_{j+2} \\
h \\
j+1
\end{array}\right)>S\binom{h_{j+1}}{h_{j}}
$$

Then if $h_{j}$. exists $h_{j+1}$ will also exist, $h_{j}{ }_{i-1}$ becomesasonof $h_{j}$. '「his contradicts the assumption that $h_{j+1}$ is a ceiling of $h_{j}$.

Lemma 8. Any arc which remains in $L$ at the end of the procedure must be present in the $\ell$-optimum partition of the polygon.

Proof. We can divide the $h$-arcs in $L$ at the end of the procedure into two groups:
(i) those which are descendant of some other arcs in the output, and
(ii) those which have no ancestor in the output.

By the definition of the descendant-ancestor relationship, the arcs in group (i) must be present in the $\ell$-optimum partition whenever their corresponding ancestors in group (ii) is present in the $\ell$-optimum partition. Hence, we have only to show that all arcs in group (ii) must be present in the $\ell$-optimum partition.

Let $V_{t}$ be the maximum vertex and the set of arcs in group (ii) be $h_{k}, h_{k 1}, \ldots, h_{j+1}, h_{j}$ such that $h_{k} / h_{k 1} / \ldots h_{j+1} / h_{3}$. Since none of these arcs has an ancestor, we must have

$$
h_{k} \text { as the ceiling of } h_{k-1}
$$

and $\quad h_{j+1}$ as the ceiling of $h_{3}$.
From the logical condition in Step 1 of the procedure, we have

$$
\begin{equation*}
w_{1}>s\binom{h_{j}+1}{h_{j}} \tag{10}
\end{equation*}
$$

From Lemma 7 and (10), we have

$$
w_{1}>s\binom{h_{j}+1}{h_{j}}>\cdots>\overbrace{h_{k-1}}^{h_{k}})>s\binom{h_{t}}{h_{k}}
$$

which implies tiat

$$
\begin{aligned}
H_{0}\binom{h_{t}}{h_{1}} & >\left[C\binom{h_{t}}{h_{k}}+H_{0}\binom{h_{k}}{h_{1}}\right] \\
& >\left[C\binom{h_{t}}{h_{k}}+C\binom{h_{k}}{h_{k-1}}+H_{0}\binom{h_{k-1}}{k_{1}}\right] \\
& >\left[C\binom{h_{t}}{h_{k}}+C\binom{h_{k}}{h_{k-1}}+\cdots+C\binom{h_{j}+1}{h_{j}}+H_{0}\binom{h_{j}}{h_{1}}\right]
\end{aligned}
$$

$=$ the cost of the $\ell$-optimum partition of the polygon.

In other words, for any arc $h_{i}$ in group (ii) of $L$, $\mathbf{i}=k, k-1, \ldots, j+1$, $j$,
all the arcs above $h_{1}$ in $L$ must be present in $\ell$-optimum partition of the upper subpolygon of $h_{i}$. Since $H_{0}\binom{h_{t}}{h_{1}}>C\binom{h_{t}}{h_{j}}+H_{0}\binom{h_{j}}{h_{1}}$, they all should be present in the $\ell$-optimum partition of the monotone basic polygon.

Theorem 2. The partition obtained by the algorithm is $\ell$-optimum.

Proof, From Theorems 3 and 4 of Part I, we know that all the $h$-arcs present in the $\ell$-optimum partition are potential $h$-arcs and hence are included in the arc -list $L$ obtained by the one-sweep algorithm, It follows from Lemmas 5 and 8 that all the arcs which are deleted from $L$ cannot be present in the $\ell$-optimum partition and all the arcs which remain in $L$ must be present in the $\ell$-optimum partition. Further, from Lemma 1, the
$\ell$-optimum partition in any subpolygon bounded by two adjacent potential $h$-arcs in $L$ must be a fan. Hence, the partition consisting of the $h$-arcs output by the algorithm and with fans in every subpolygons bounded by two adjacent arcs in $L$ must be $\ell$-optimum.

Let us examine how much time we spend in executing the algorithm,

Step 0 and Step 1 each scans the polygon once, and hence takes $O(n)$ time. Since there are at most $n-3$ arcs in $L$, Step 2 also takes $O(n)$ time. There are three nested loops in the procedure. The innermost one is in Step 6, the middle one spans from Step 1 to Step 3, while the outermost one spans from Step 1 to Step 5. Whenever the innermost loop is cxecuted once, a potential h-arc is deleted from L. Whenever the middle loop is executed once (i.e. the "then" part of Step 3 is executed once), a potential $h$-arc is condensed into its father. Once an arc is deleted or condensed, it will never be examined again. Since there are at most $n-3$ potential $h$-arcs in $I$, the total number of executions in Step 2 and Step 3 is $O(n)$. The outermost loop will also be executed at most (n-3) times. Hence the whole algorithm will finish its work in $O(n)$ time.

## 3. The Convex Polygon

Theremay be several local maximum vertices in general convex polygon. Let us still draw the polygon in such a way that the global minimum vertex is at the bottom. From Theorem 4 of part $I$, we know that all potential $h$-arcs are still compatible in a general convex polygon. However, unlike those in a monotone polygon, the potential $h$-arcs no longer form a linear list. Instead, they form a tree, called an arc-tree. In Fig. 1la, there is a 12 -gon with 6 potential $h-a r e s$ and they are labelled as $h_{2}, h_{3}, h_{4}, h_{5}$, $h_{6}$, and $h_{7}$. (Note that we also obtain $V_{4}-V_{3}, V_{7}-V_{6}$ and $V_{6}-V_{8}$ from the one- sweep algorithm. In order to have a simpler example, let us assume that all these three arcs are unstable and hence are not shown in Fig. lla.) To get a better feeling of the arc-tree, we can redraw the 12-gon as shown in Fig. 11b. Again, we regard $V_{1}$ as a degenerated arch $1, V_{12}$ as a degenerated arc $h_{8}$, and $V_{11}$ as a degenerated $\operatorname{arc} \mathbf{h}_{9}$,

The father-son relationship still holds for the $h$-arcs in a general polygon, and we can also define supporting weights of the arcs in a similar way. The only difference is that the ceiling of a subpolygon may consist of more than one arc. Before we can calculate the supporting weight of any arc, we must process all the arcs above it, i. c. all the arcs in its upper subpolygon. Hence, we can do a post-order traversal through the arc tree. Let us consider the following two examples. Again, for simplicity, we assume that all arcs have distinct positions in the examples.

(a)

(b)

Fig. 11. A general 12-gon.

## Example. . ${ }^{\mathbf{3} .}$

We first compare

$$
H_{0}\binom{h_{8}}{h_{5}}+H_{0}\binom{h_{5}}{f_{5}}=H_{0}\binom{h_{8}}{f_{5}}
$$

Fig. 12. Illustrations for Example 3.
12a. To find $f_{5}$.

Assume $h_{4} / f_{5}$, we compare
$H_{0}\binom{h_{5}}{h_{4}}+H_{0}\binom{h_{4}}{f_{4}}=H_{0}\binom{h_{5}}{f_{4}}$

Fig. 12b. COo fir $\mathrm{Hdf}_{4}$.

Assume $h_{3} / f_{4}$ and $f_{5} / f_{4}$, wc condense $h_{5}$ into $h_{4}$,
$H_{0}\binom{h_{8}}{h_{5}}+H_{0}\binom{h_{5}}{h_{4}}+H_{0}\binom{h_{4}}{f_{54}}=H_{0}\binom{h_{8}}{f_{54}}$
or
$C\binom{h_{8}}{h_{4}}+H_{0}\binom{h_{4}}{f_{54}}=H_{0}\binom{h_{8}}{f_{54}}$

Fig. 12c. To find $f_{54}$.

Before we can process $h_{3}$, we have to process $h_{7}$ and $h_{6}$ first. Hence, the next comparison is:
$H_{0}\binom{h_{9}}{h_{7}}+H_{0}\binom{h_{7}}{f_{7}}=H_{0}\binom{h_{9}}{f_{7}}$

Fig. 12d. To find $f_{7}$.

Assume $h_{6} / f_{7}$, we compare

$$
H_{0}\binom{h_{7}}{h_{6}}+H_{0}\binom{h_{6}}{f_{6}}=H_{0}\binom{h_{7}}{f_{6}}
$$

Fig. 12 e . To $\mathrm{find} \mathrm{f}_{6}$.

We have $h_{3} / f_{6}$ and $f_{7} / f_{6}$, we condense $h_{7}$ into $h_{6}$,
$H_{0}\binom{h_{9}}{h_{7}}+H_{0}\binom{h_{7}}{h_{6}}+H_{0}\binom{h_{6}}{f_{76}}=H_{0}\binom{h_{9}}{f_{76}}$
or
$C\binom{h_{9}}{h_{6}}+H_{0}\binom{h_{6}}{f_{76}}=H_{0}\binom{h_{9}}{f_{76}}$

Fig. 12 f. To find $f_{76}$.

Assume $h_{3} / f_{76}$ and next we process the arc $h_{3}$, using both $h_{4}$ and $h_{6}$ as the ceilings of $h_{3}$,

$$
H_{0}\binom{h_{4}, h_{6}}{h_{3}} \text { t } H_{0}\binom{h_{3}}{f_{3}}=H_{0}\binom{h_{4}, h_{6}}{f_{3}}
$$

Fig. 12 g. . $\circ$ find $f_{3}$.

Suppose $h_{2} / f_{3}$ and $f_{54} / f_{76} / f_{3}$, we first condense $h_{5}$ and $h_{4}$ into $h_{3}$ and we get

$$
C\binom{h_{8}, h_{6}}{h_{3}}+H_{0}\binom{h_{3}}{f_{544}}=H_{0}\binom{h_{8}, h_{6}}{f_{543}}
$$

Fig. 12 h. To find $f_{543}$.

Now, $h_{2} / f_{543}$ and $f_{76} / f_{543}$, so we condense $h_{7}$ and $h_{6}$ into $h_{3}$ and obtain
$C\binom{h_{8}, h_{9}}{h_{3}}+H_{0}\binom{h_{3}}{f_{54763}}=H_{0}\binom{h_{8}, h_{9}}{f_{54763}}$

Fig. 12i. 'To find $f_{54763}$.

Assume $h_{2} / f_{54763}$ nod we compare

$$
H_{0}\binom{h_{3}}{h_{2}}+H_{0}\binom{h_{2}}{f_{2}}=H_{0}\binom{h_{3}}{f_{2}}
$$

Fig. 12 j. 'To find $f_{2}$.

Suppose $\cdot h_{1} / f_{2}$ and $f_{54763} / f_{2}$, we condense $h_{3}$ and its descendants into $\mathrm{h}_{2}$ and get

$$
C\binom{h_{8}, h_{9}}{h_{2}}+H_{0}\binom{h_{2}}{f_{547632}}=H_{0}\binom{h_{8}, h_{9}}{f_{547632}}
$$

Fig. 12k. To find $f_{547632}$.

If $h_{1} / f_{5476}$, , the $\ell$-optimum partition of the whole polygon consists of all six $h-\operatorname{arcs} h_{2}, h_{3}, h_{4}, h_{5}, h_{6}$, and $h_{7}$. If $f_{547632} / h_{1}$, all six $h-a r e s$ will beremoved and the $\ell$-optimum partition is a fan.

## Example 4

We first compare
$H_{0}\binom{h_{8}}{h_{5}}+H_{0}\binom{h_{5}}{f_{5}}=H_{0}\binom{h_{8}}{f_{5}}$

Fig. 13. Illustrations for Exam ale 4. 13a. To find $f_{5}$.

Assume $h_{4} / f_{5}$ and we compare

$$
\mathrm{H}_{0}\binom{\mathrm{~h}_{5}}{\mathrm{~h}_{4}}+\mathrm{H}_{0}\binom{\mathrm{~h}_{4}}{f_{4}}=\mathrm{H}_{0}\binom{\mathrm{~h}_{5}}{\mathrm{f}_{4}}
$$

Fig. 13b. To find $f_{4}$.

Let $h_{3} / f_{4}$ and $f_{4} / f_{5}$, so we compare
$H_{0}\binom{h_{9}}{h_{7}}+H_{0}\binom{h_{7}}{f_{7}}=H_{0}\binom{h_{9}}{f_{7}}$

Fig. 13c. To find $f$
$h_{6} / h_{7}$ and we compare

$$
H_{0}\binom{h_{7}}{h_{6}}+H_{0}\binom{h_{6}}{f_{6}}=H_{0}\binom{h_{7}}{f_{6}}
$$

Fig. 13 d . To find $\mathrm{f}_{6}$.

We have $h_{3} / f_{6}$ and $f_{6} / f_{7}$, so our next comparison will be

Assurnch $h_{2} / f_{43}, f_{43} / f_{6}$, and $f_{43} / f_{5}$, we proceed to process $h_{2}$.

$$
\mathrm{H}_{0}\binom{\mathrm{~h}_{3}}{\mathrm{~h}_{2}}+\mathrm{H}_{0}\binom{\mathrm{~h}_{2}}{\mathrm{f}_{2}}=\mathrm{H}_{0}\binom{\mathrm{~h}_{3}}{f_{2}}
$$

Fig. 13 g . To find $\mathrm{f}_{2}$.

Assume $h_{1} / f_{2}$ and $f_{43} / f_{2}$, we condense $h_{3}$ into $h_{2}$,

$$
C\binom{h_{5}, h_{6}}{h_{2}}+H_{0}\binom{h_{2}}{f_{432}}=H_{0}\binom{h_{5}, h_{6}}{f_{432}}
$$

Fig. 13 h . To find $\mathrm{f}_{43}$.

Suppose $f_{432} / h_{1}, w \quad$ c remove $h_{2}$ as well as its descendants $h_{3}$ and $h_{4}$. Assume $f_{6} / f_{5}$ and $f_{6} / h_{1}$, weremove $h_{6}$ from the polygon, Now, we have $f_{7} / f_{5}$ and $f_{7} / h_{1}$, so we remove $h_{7}$ from the polygon. Finally, we have $h_{1} / f_{5}$, and the $\ell$-optimum partition of the polygon consists of one h-arc $\mathrm{h}_{5}$.

Fig. 13i. The optimum partition.

From the above two examples, we have the following observatons.
(1) Before we can process a potential $h$-arc, wc have to process all the arcs above it. Hence, wc should do a post-order traversal, starting at the root of the are tree, i. e. the degenerated arc $h_{1}$.
(2) Whenever wc do a condensation or deletion, wc always pick the ceiling arc which has the highest floor first, i. c. the one with the largest supporting weight. Hence, wc should kc $p$ track of the order of the ceiling arcs.
(3) Once a ceiling arc $h_{j}$ of $h_{i}$ is removed or condensed, the ceiling arcs of $h_{j}$ becomethe ceiling arcs of $h_{i}$ and whave to updatethe order of all the ceiling arcs of $h_{i}$.

One way of keeping track of the order of the ceiling arcs is to keep them in a priority queue.

Now, let us outline the algorithm for finding the optimum partition of a general convex polygon.

1. Get all the potential $h$-arcs of the polygon by the one-sweep algorithm. (All the $h$-arcs form a tree, with the root at the bottom. Let the arc-tree be T.)
2. Process the $h$-arcs, one by one, from the leaves to the root. (We always process the children before we process the father, and we always obtain the optimum partition of the subpolygon bounded below by the arc being processed.)
3. Let $h_{R}$ be the arc currently being examined, $U_{R}$ be the set of arcs immediately above $h_{R}$, and $h_{N}$ be the arc immediately below $h_{R}$ in $T$. If $h_{R}$ is negative in the subpolygon bounded above by the arcs in $U_{R}$ and below by $h_{N}$, delete $h_{R}$, else go to step 5 .
4. Once $h_{R}$ and its descendants are deleted, we exarnine the arcs in $\mathrm{U}_{\mathrm{R}}$ to sec if we can deletemore arcs. If yes, w delete the arc with the largest supporting weight; then we include its celing ares into $U_{R}$ and repeat this step. Otherwise, we move to process the next arc.
5. Now, $h_{R}$ is positive in the smallest subpolygon. If there exists some arc in $U_{R}$, say $h_{j}$, such that

$$
S\binom{U_{R}}{h_{R}}<\text { the supporting weight of } h_{j}
$$

we will pick the arc with the largest supporting weight in $U_{R}$, condense it with its descendants into $h_{R}$ and include all its ceiling arcs into $U_{R}$. Then we compare the cost of the partition with $h_{R}$ and its descendants against that of the fan in the subpolygon bounded above by the arcs in $\mathrm{U}_{\mathrm{R}}$ and below by $\mathrm{h}_{\mathrm{N}}$. If the fan is $\ell$-optimum in the subpolygon, we remove $h_{R}$ as well as all its descendants from $T$, and we exarnine the arcs in $U_{R}$ to see if we can delete any more arcs. Otherwi se, we examine the arcs in $U_{R}$ to see if we can condense any more arcs.
6. Now, $S\binom{U_{R}}{h_{R}} \geq$ the supporting weight of every arc in $U_{R}$. The arcs in $U_{R}$ are the ceiling arcs of $h_{R}$ and $S\binom{U_{R}}{h_{R}}$ is the supporting weight of $h_{R}$. We move to process the next arc.

Before prescnting the algorithm, let us describe a recursive procedure to process the potential h-arcs of any subpolygon.

## Procedure PARTITION (ROOT)

Input: consists of a set of potential h-arcs of a subpolygon. The sc arcs are arranged in the form of an arc tree, like the one shown in Fig. llb. The root of the tree is passed to the procedure via the argument ROOT.
out put: consists of a set of the potential $h$-arcs which appear in the $\ell$-optimum partition of the subpolygon. We can divide that arcs into two types: (i) those arcs which are descendants of some other arcs in the set and (ii) those arcs which have no ancestor in the set, The arcs in type (i) are condensed into their ancestors and can be traced out from the arcs in type (ii). The arcs in type (ii) are called ceiling arcs and are kept in a reduced arc tree. The root of the arc tree is passed back to the caller via the parameter ROOT.

Step 0 Let the arc at the root of the inputaretreebe $\mathrm{h}_{\mathrm{N}}$; MIN-WEIGII'I : = the weight of theminimum of the two vertices of $h_{N}$;
$T:=$ an arc tree with only one arc, $h_{N}$;

Step $1 \quad$ For each arc immediately above $h_{N}$ in the input arc-tree Do

## Begin

Step la Let the arc to be processed be $h_{R}$;
If there exists a non-degenerated arc above $h_{R}$
then go to Step lb
else go to Step lf;
Comment: $h_{R}$ is immediately above $h_{N}$.

Step 1b
PARTITION ( $\mathrm{h}_{\mathrm{R}}$ );
Let the subtrce returnedbe $\mathrm{T}^{\prime}$;
Comment: Before processing $\mathbf{h}_{\mathrm{R}}$, the subtrees of $\mathbf{h}_{\mathrm{R}}$ are first processedrecursively.

Step le Let $U_{R}$ bethesctofarcs immediately above $h_{R}$ in $T^{\prime}$;
Calculate $S\binom{\mathrm{U}_{\mathrm{R}}}{\mathrm{h}_{\mathrm{K}}}$;
If $\mathbf{s}\binom{U_{R}}{h_{R}} \geq$ MIN-WEICIII
then go to Step ld
else go to Step le.
Step ld Remove $h_{R}$ from $T^{\prime}$;
while (there exists a non-degenerated arc, $h_{j}$, in $U_{R}$ ) and
(the supporting weight of $h_{j} \geq$ MIN-WEICiHT) Do
Begin
Remove $h_{j}$ from UR ;
Remove $\underset{3}{ }$. from $\mathbf{T}^{\prime}$;Include all ceiling arcs of $h_{j}$. into $U_{R}$;end;
Insert the forest $T^{\prime}$ into $T$ such that all arcs in $U_{R}$ areimmediatcly above $\mathbf{h}_{\mathbf{N}}$ in $\mathbf{T}$.
Go to Step li.
Step le If (there exists a non-degencratcd arc in $U_{R}$ ) and (its sup-porting weight $>$ the supporting weight of $h_{R}$ )
then
Begin
Among all the arcs in $U_{R}$, pick the one with maximum
supporting weight;
Let it be ${ }_{3}$.;
Condense $\underset{3}{ }$. into $h_{R}$ and remove it from $T^{\prime}$;
Include all ceiling ares of $h_{j}$ into $U_{R}$;
Fix up the trec $\mathrm{T}^{\prime}$ so that all the ceiling ares of $\mathrm{h}_{\mathrm{j}}$ are
immediately above $h_{\mathbf{R}}$ in $\mathbf{T}^{\prime}$;
go to Ste plc;
end

## Begin

Record $S\binom{U_{R}}{h_{R}}$ as the supporting weight of $h_{R}$ and all arcs in $U_{R}$ as the ccil.ing arcs of $h_{R}$; insert $T$ ' into $T$
so that $h_{R}$ is immediately above $h_{N}$ in $T$;
go to Step li ;
end.
step lf Let $h_{C}$ be the degenerated arc above $h_{R}$;
Calculate $S\binom{h_{C}}{h_{R}}$;
If $S\binom{h_{C}}{h_{R}} \geq$ MIN- WEIGHT
then.go to Step $1 g$
elsc go to Step 1 lh .
step lg Remove $h_{R}$;
Insert $h_{C}$ immediately above $h_{N}$ in $T$.
go to Step li .
Step $h$ Record $S\binom{h_{C}}{h_{R}}$ as the supporting weight of $h_{R}$ and $h_{C}$ as the ceiling arc of $h_{R}$; insert the subtree with $h_{R}$ and ${ }^{h_{C}}$ into $T$ so that $h_{R}$ is immediately above $h_{N}$ in $T$.

Step li End.

Step 2. Return $T$ with root stored in ROOT to caller.

Now, the details of the algorithm to find an optimum partition of a convex polygon is presented.

Algorithm II
Input consists of $n$ positive integers, which are the weights of the n vertices of an $\mathbf{n}$-gon. $W[1]$ is the weight of the minimum vertex and $W[i+1]$ is the neighbor of $W$ [i] of the $n$-gon going in the clockwise direction.
out put consists of a tree of potential $h$-arcs which exist in the $\ell$-optimum partition of the $\mathbf{n}$-gaon.

Step 0 For i : = 2 step 1 until $N$ do

$$
C P[i]:=\sum_{j=1}^{i-1} W[j] . W[j+1] ;
$$

CP [1]: = $\mathbf{0}$;
Comment: Thesum of adjacent products $\mathbf{W}$ [i]: $\mathbf{W}[j]$ can be obtained from $C P[j]-C P[i]$ for $\mathbf{1} \leqslant \mathbf{i}<\mathbf{j} \leqslant \mathbf{N}$.
step 1 Apply the one-sweep algorithm to obtain a trec of arcs. Let this are tree be $T$.

Comment: $T$ contains all potentialh-arcsin the $n-g o n$.

Step 2 From T, remove those arcs which arc not potential
h-arcs;

If T is empty
thengo to Step 6.
else go to Step 3.
Step 3 Insert the degenerated are $h_{1}$ with weight W|1] to thebottom of the trec, as the root of the tree;Insert a degenerated are with the local maximum weightat the tip of each corresponding branch of the arc tree.
Step PARTITION (hl);
Comment: $\mathbf{h} 1$ is the root of $T$; when returned fromPARTITION, T will contain all the ceiling arcs with theirdescendants in the $\ell$-optimum partition.
Step 5 Remove all degenerated arc s.
Step $6 \quad$ Output $T$ and stop.

This algorithm has beenimplemented in Pascal and the listing of the computer program is given in Appendix II.

Theorem 3. The partition of the general convex $n$-gon obtained by the algorithm is $\ell$-optimum.

Proof. Using arguments similar to those in Theorem 2, we can first prove that all the potential $h$-arcs which are deleted from the arc-tree cannot be present in the $\ell$-optimum partition, then we prove that any arc which is left in the arc-tree at the end of the algorithm must be present in the $\ell$-optimum partition. Hence, the partition consisting of the $h$-arcs output by the algorithm and with fans in the subpolygons bounded by a potential $h$-arc and the arcs immediately above it in the output arctree must be I-optimum.

Let us examinc how much time wespend in executing the algorithm. Steps 0 and 1 each scans the polygon once, and hence takes $O(n)$ time. Since there arc at most $n-3$ arcs in $T$, Step 2 also takes $O(n)$ time, There will be a recursive procedure call for each arc in $T$ (except the leaf nodes). Inside each procedure call, there are two nested loops. The innermost loop is the "while" loop in Step ld and the outer one spans from Steps le to le. Whenever the innermost loop is executed once, a potential $h-a r c$ is deleted from $T$. Whenever the outer loop is executed once (i.e. the '-'then" part of Step le), a potential h-arc is condensed into its father. Once an arc is deleted or condensed, it will never bc examined again. In order to carry out the deletion and condensation efficiently, we cannot examine all the arcs in $U_{R}$ each time we go through the loop. Hence, we need to order the arcs in $U_{R}$ in a priority queue and it takes $O(\log n)$ to update the queue each time. Hence, it takes $O(n \log n)$ time in executing Step 4 of the algorithm. Steps 5 and 6 each takes $O(n)$ time. Hence, the whole algorithm takes $O(n \log n)$ time to find the $\ell$-optimum partition.

## 4. A closer look at the optimum partitions

Wc now present some theorems which enable the algorithm to divide the polygon into several subpolygons and hence can improve the average performance of the algorithm. These theorems have also been mentioned in [4] without detailed proofs.

Let us consider the polygons where there are two or more vertices with equal weights $\mathbf{w}_{1}$.

Lemma 9. For every choice of $\mathrm{Vl}, \mathrm{V}_{2}$, . . (as prescribed in Part I), if 'the weights of the vertices satisfy the condition

$$
w_{1}=w_{2}<w_{3} \leq \cdots \leq w_{n},
$$

then $V_{1}-V_{2}$ exists in every optimum partition of the $n$-gon.
Proof. The lemma is true if $\mathrm{V}_{1}-\mathrm{V}_{2}$ is a side of the n -g-on. Hence, we can assume that $\mathrm{V} 1, \mathrm{~V}_{2}$ are not adjacent to the same side of the $n$-gon.

The proof is by induction on the size of the $n$-gon. The lemma is true for a triangle and a quadrilateral. Assume that the lemma is true for all $k$-gons ( $3 \leq k \leq n-1$ ) and consider the optimum partitions of an n-gon.

By Lemma 3 of Part I, we know that there are at least two vertices with degree two in each optimum partition of the n-gon. We have the following two cases,
(i) In an optimum partition of an n-gon, one of the vertices with degree two, say $\mathrm{V}_{\mathrm{i}}$, has weights larger than $\mathrm{w}_{1}$. In this case, we can form an ( $\mathrm{n}-1$ )-gon by removing $\mathrm{V}_{\mathrm{i}}$ with its two sides. By induction assumption, $V_{1}-V_{2}$ is present in every optimum partition of the ( $n$-1)-gon.
(ii) Consider the complementary case of (i), i. c. all vertices with degree two have weights equal to $w l$ in an optimum partition of the n-gon. In other words, $V 1$ and $V_{2}$ arc the only two vertices with degree two in that optimum partition, as shown symbolically in Fig. 14a. Note that every arc in the optimum partition must dissect the $n$-gon into two subpolygons in such a way that $\mathrm{V}, \mathrm{V}_{2}$ can never appear in any subpolygon together, else there will be more than two vertices with degree two in the optimum partition. In Fig. 14 b , we show a partition of the $n$-gon in which $V_{1}$ and $V_{2}$ are connected. Let us denote the $n-2$ triangles in Fig, 14a by $P_{1}, P_{2}, \ldots, P_{n} 2^{\text {. Except }} P_{1}$ and $P_{n-2}$, all the other $n-4$ triangles are made up of one side and two arcs each. For each of these n-4 triangles, we can find a unique triangle in Fig. 14b such that they both consist of the same side. We use $P_{i}^{\prime}$ to denote the image of $P_{i}$ in Fig. 14b. The only two triangles left unmatched in Fig. 14b are $V_{1} V_{a} V_{2}$ and $V_{1} V_{2} V_{i}$ and they are the images of $P l$ and $P_{n-2}$, respectively. Let the cost of $P_{i}$ be $C_{i}$ and the cost of $P_{1}$, be $C_{1} C^{\prime}$, Since $C_{i}^{\prime} \leq C_{i}$ for $1 \leq i \leq n-2$, the partition in Fig, 14b is cheaper than that in Fig. 14a and we have contradiction.

(a)

(1)

Fig. 14

Theorem 4. For every choice of $V_{1}, V_{2}, \ldots$ (as prescribed in Part I), if the weights of the vertices satisfy the condition

$$
\mathrm{w}_{1}=\mathrm{w}_{2}<\mathrm{w}_{3} \leq \mathrm{w}_{4} \leq \cdots \leq \mathrm{w}_{\mathrm{n}}
$$

then every optimum partition of the n-gon must contain a triangle $V_{1}^{V} \mathbf{V}$ for some vertex $V_{p}$ with weight equal to $w_{3}$. Note that if $w_{1}=w_{2}<w_{3}$ $<w_{4} \leq \ldots s w_{n}$, then every optimum partition must contain the triangle $\mathrm{V}_{1} \mathrm{~V}_{2} \mathrm{~V}_{3}$ since there is a unique choice of $\mathrm{V}_{3}$.

Proof. Similar to Lemma9, we can prove this theorem by induction on the size of the n-gon. The theorem is true for any triangle or quadrilateral satisfying the above condition. Assume the theorem is true for all k-gons ( $3 \leq k \leq n-1$ ) and consider the optimum partitions of an n-gon.

From Lemma 9, we know that $V 1, V_{2}$ are always connected in every optimum partition. Hence, without loss of generality, we can assume $\mathrm{Vl}, \mathrm{V}_{2}$ to be adjacent to the same side of the $n$-gon. Again, we have the following two cases.
(i) In an optimum partition, one of the vertices with degree two, say $\mathrm{V}_{1}$, has weight larger than $w_{3}$. In this case, we can remove $V_{1}$ with its sides and form an (n-1)-gon. By induction assumption, every optimum partition of the ( n - 1)-gon contains a triangle $\mathrm{Y}_{2} V_{\mathbf{P}}^{\mathbf{V}}$ for some vertex $\mathbf{V}_{\mathbf{P}}$ where $\mathbf{w}_{\mathbf{P}}={ }_{\mathrm{w}}^{\mathbf{w}}$.
(ii) Consider the complementary case of (i), in an optimum partition of the $n$ - gon, all vertices with degree two have weights less than or equal to $w_{3}$. Since $V_{1}-V_{2}$ is a side of the $n$-gon, for $n \geq 4$, either $V l$ or $V_{2}$ (but not both) can have degree two, We have the following two subcases:
(a) If there are more than one vertex whose weight equals $w_{3}$, we can form an (n-1)-gon by removing one of those degree two vertices whose weight equals $w_{3}$, By induction assumption, every optimum partition of the ( $\mathrm{n}-1$ )-gon contains a triangle $\mathrm{V}_{1} \mathrm{~V}_{2} \mathbf{V}_{\mathrm{p}}$ for some vertex VP with $\underset{\mathrm{P}}{\mathbf{w}}=\mathrm{w}_{3}$, (b) There exists only one vertex of weight $w_{3}$, In this case, there must be only two vertices with degree two in the optimum partition of the n-gon. These two vertices are $\mathrm{V}_{3}$ and either Vl or $\mathrm{V}_{2}$. Without loss of generality, we can assume Vl has degree 2. The situation is shown symbolically in Fig. 15a. Again, every arc in the optimum partition must dissect the n-gon in such a way that $V_{1}$ and $V_{3}$ can never appear in any subpolygon together, In Fig. $15 b$, we show a partition containing the triangle $\mathbf{V}_{1} \mathbf{V}_{\mathbf{2}} \mathbf{V}_{3}$. Using arguments similar to those in the proof of Lemma 9, we can show that the partition in Fig, $15 b$ is cheaper and we obtain a contradiction.

(a)

(b)

Fig. 15

Theorem 5. For every choice of $\mathrm{V}, \mathrm{V}_{2}, \ldots$ (as prescribed in Part $I$ ), if the weights of the vertices of the n-gon satisfy the following condition,

$$
w_{1}=w_{2}=\cdots=w_{k}<w_{k+1} \leq \cdots \leq w_{n}
$$

for some $k, 3 \leq k \leq n$, then every optimum partition of the n-gon contains the k-gon $\mathrm{V}_{1}-\mathrm{V}_{2}-\cdots-\mathrm{V}_{\mathrm{k}}$.

Proof. The proof is by induction on the size of the n-gon. The theorem is true for any triangle and quadrilateral. Suppose the theorem is true for all polygons with (n-l) sides or less and consider the optimum partitions of an n-gon.

From Lemma 3 of Part $I$, there exist at least two vertices having degree two in every optimum partition. We have the following two cases.
(i) In an optimum partition of the $n$-gon, one of the vertices with degree two, say $V_{i}$, has weight larger than $w_{1}$. In this case, we can remove the vertex $V_{i}$ with its two sides and obtain an (n-1)-gon. By induction assumption, every optimum partition of the $(n-1)$-gon contains the $k-g o n V_{1}-V_{2^{-}} \cdots-V_{k}$.
(ii) Consider the complementary case of (i), i. e., all the vertices with degree two have weights equal to $\underset{1}{ }$, in an optimum partition. Let two of these vertices be $V_{i}, V_{j}$. We have the following two subcases:
(a) $k>3$. We first form an (n- 1)-gon by removing $V_{1}$. and its two sides.

There are (k-1) vertices with weights equal to wl in the (n-1)-gon. By induction assumption, every optimum partition of the ( $n-1$ )-gon contains the ( $k-1$ )gon which includes $V_{j}$ as one of its vertices. Since $V_{j}$ has degree two in the optimum partition, its two neighboring vertices, say $V_{X}$ and $V_{Y}$, must also have weights equal to $w l$ and the $\operatorname{arc} V_{x}-V_{y}$ exists in the optimum partition (Fig. 16). Similarly, we can remove the vertex $V_{j}$ with its two sides $V_{j} .-V$ and $V_{j}-V_{y}$ and form an (n-1)-gon. By induction assumption, every optimum partition of the ( $n$ - 1 )-gon contains the (k-1)-gon formed by the (k-1) vertices with weights equal to $w_{1}$ in the (n-l)-gon and $V_{1}$ is one of the vertices in the (k- l)-gon. Now, by pasting the triangle $\mathrm{V}_{\mathrm{x}} \mathrm{V}_{\mathrm{j}} \mathrm{V}_{\mathrm{y}}$ and the (k-l)-gon together, we form a k-gon which includes all the vertices with weight equal to $w_{1}$ in the $n$-gon and this k-gon is contained in the optimum partition of the $n$-gon.

Fig. 16
(b) $k=3$. In this case, we have $w_{1}=w_{2}=w_{3}<w_{4} \leq \ldots \leq w_{n}$.

Without loss of generality, we can assume $\mathrm{V}_{1}$ and $\mathrm{V}_{2}$ both have degree two in an optimum partition. Again, we can form an ( $\mathrm{n}-1$ )-gon by removing $\mathrm{V}_{1}$ and its two sides. By Lemma $9, \mathrm{~V}_{2}$ and $\mathrm{V}_{3}$ are connected in every optimum partition of the ( $n-1$ )-gon. Since $V_{2}$ has degree two, $V_{2}-V_{3}$ must be a side of the $n$-gon. Next, we can remove $V_{2}$ with its two sides and form an (n-1)gon. By Lemma $9, \mathrm{~V}_{1}, \mathrm{~V}_{3}$ are connected by a side of the $n$-gon. The situation is shown in Fig. 17a. Then, the partition in Fig. 17b is cheaper because

$$
\mathrm{T}_{123}+\mathrm{T}_{12 \mathrm{y}} \leq \mathrm{T}_{13 \mathrm{x}}+\mathrm{T}_{23 \mathrm{y}}
$$

and

$$
C\left(w_{1}, w_{x}, \ldots, w_{y}\right)=C\left(w_{3}, w_{x}, \ldots, w_{y}\right)
$$

(a)

(b)

Fig. 17

Now, whenever we have three or more vertices with weights equal to $w_{1}$ in the $n$-gov, we can decompose the $n$-gone into subpolygons by forming the $k$-gown in Theorem 5. The partition of the k-gon can be arbitrary, since all vertices of the k-gon are of equal weight. For any subpolygon with two vertices of weights equal to ${ }^{1}$, we can always apply Theorem 4 and decompose the subpolygon into smaller subpolygons. Hence, we have only to consider the polygons with a unique choice of $V_{1}$, i. e., each polygon has only one vertex with weight equal to $w_{1}$,

Because of Theorems 4 and 5, Theorems 1 and 3 of Part $I$ can be generalized as follows.

Theorem 6. For every choice of $V_{1}, V_{2}, \ldots$ (as prescribed in Part $\left.I\right)$, if the weights of the vertices satisfy the condition

$$
w_{1}<w_{2} \leq w_{3} \leq \cdots \leq w_{n}
$$

then $V_{1}-V_{2}$ and $V_{1}-V_{3}$ exist in ry optimum partition of the n-gon.

Theorem 7. Let $V_{x}$ and $V_{z}$ be two arbitrary vertices which arc not adjacent in a polygon, and $V_{w}$ be the smallest vertex from $V_{x}$ to $V_{z}$ in the clockwise manner $\quad\left(\underset{\mathrm{W}}{\mathrm{V}} \neq \mathbf{x}, \mathbf{\mathrm { V }} \neq \mathrm{V}_{\mathrm{z}}\right)$, and $\mathrm{V}_{\mathrm{Y}}$ be the smallest vertex from $\mathrm{V}_{\mathrm{z}}$ to $\mathrm{V}_{\mathrm{x}}$ in the clockwise manner $\left(V \neq V_{x}, V_{y} \neq V_{z}\right)$. This is shown in Fig. 18 where we assume that $\mathrm{X}_{\mathrm{x}}<\mathrm{V}_{\mathrm{z}}$ and $\mathrm{V}_{\mathrm{y}}<\mathrm{V}_{\mathrm{w}}$. The necessary condition for $V_{x}-V_{z}$ to exist as an $h$-arc in any optimum partition is

$$
\mathrm{w}_{\mathrm{y}}<\mathrm{w}_{\mathrm{x}} \leq \mathrm{w}_{\mathrm{z}}<\mathrm{w}_{\mathrm{w}}
$$

Fig. 18

From Theorem 7, we know that any arc which exists as an h-arc in some optimum partition must be a potential $h$-arc. In other words, the h-arcs in every optimum partition will be gencrated by the one-sweep algorithm. Hence, by modifying the condition in steps 1 c and ld of the procedure Partition to favor partitions with morc h-arcs, wc can obtain other optimum partitions which consist of more $h$-arcs than the P-optimum partition.

## 5, Conclusion

The problem to find the optimum order of computing a chain of matrices has been around for several years [2]. It has been used as a typical example to illustrate the dynamic programming technique in many textbooks [1][3]. In this paper, a new approach is used to solve the problem. Instead of tackling the matrix chain product problem directly, it is transformed into the problem of partitioning a convex polygon and a tailor-made algorithm for finding the optimum partition is developed. The algorithm takes $O(n \log n)$ time and $O(n)$ space. For those who want to trade optimum solution for shorter execution time, an $O(n)$ heuristic algorithm has been presented in [5]. This heuristic algorithm is very simple to implement and its error bound given explicitly as a function of the number of sides of the convex polygon and the ratio of the weights of the largest vertex to that of the smallest vertex. The worst error ratio is less than $15 \%$.
