

## Procedures Versus Algorithms

There are two senses in which a TM accepts a language.

1. The TM accepts the strings in the language (by final state), but does not halt on some of the strings not in the language.
  - ◆ Thus, we can never be sure whether those strings are rejected, or eventually will be accepted.
  - ◆ A language accepted in this way is called *recursively enumerable* (RE).
  - ◆ Note: this notion is the normal “accepted by a TM” notion.
  - ◆ The TM is sometimes referred to as a *procedure*.
2. The TM accepts by final state, but halts on every string, whether or not it is accepted.
  - ◆ A language accepted this way is called *recursive*.
  - ◆ As a problem, the question is called *decidable*.
  - ◆ The TM is called an *algorithm*.

## Plan

1. Show a particular language not to be RE.
  - ◆ Like the “hello-world” argument, we show no TM can tell whether a given TM halts on a given input — the proof is by “diagonalization,” or self-reference.
2. Use the non-RE language from (1) to show another language to be RE, but not recursive.
  - ◆ Trick: if a language and its complement are both RE, then they are both recursive.
  - ◆ Thus, if a language  $L$  is RE, but its complement is not, then  $L$  is not recursive.

## TM's as Integers

We shall focus on TM's whose input alphabet is  $\{0, 1\}$ . Each such TM can be represented by one or more integers, using the following code:

- Assume the states are  $\{q_1, q_2, \dots\}$ . Represent  $q_i$  by  $0^i$ .

- Assume the tape symbols are  $\{X_1, X_2, \dots\}$ , where the first three of these are 0, 1, and  $B$ , in that order. Represent  $X_i$  by  $0^i$ .
- Represent directions  $L$  and  $R$  by 0 and 00, respectively, and refer to them as  $L = D_1$ ,  $R = D_2$ .
- Represent a rule of the TM  $\delta(q_i, X_j) = (q_k, X_l, D_m)$  by  $0^i 10^j 10^k 10^l 10^m$ .
- Represent the whole TM by  $111C_111C_211 \dots 11C_n111$ , where  $C_i$  is the code for one of the  $\delta$  rules, in any order.
  - ◆ This string is some integer in binary, so we can call the TM  $M_i$ , where  $i$  is that integer.
- Conversely, every integer  $i$  can be said to describe some TM  $M_i$ .
  - ◆ If  $i$  in binary is not of the right form  $(111code \dots)$ , then  $M_i$  is the TM with no moves. Thus,  $H(M_i)$  is  $L(0+1)^*$ .
  - ◆ Note that many integers represent the same TM, but that is neither good nor bad.

### The Diagonalization Language

Define  $L_d$  to be the set of binary strings  $w$  with the following properties:

1. First, let  $i$  be the integer that is  $1w$  in binary.
  - ◆ Refer to  $w$  as the “ $i$ th string,” or  $w_i$ .
2. Then  $w_i$  is in  $L_d$  if and only if  $w_i$  is not in  $H(M_i)$ .

### Proof $L_d$ is not RE

Suppose  $L_d$  is RE. Then  $L_d = H(M)$  for some TM  $M$ .

- Since the input alphabet of  $M$  is  $\{0, 1\}$ ,  $M$  is  $M_j$  for at least one value of  $j$ .
- Let  $x$  be the  $j$ th string; i.e.,  $1x$  is  $j$  in binary.
- Question: is  $x$  in  $L_d$ ?
  - ◆ Suppose so. Then  $x$  is **not** in  $H(M_j)$ , by definition of  $L_d$ . But  $H(M_j) = H(M) = L_d$ , so  $x$  is **not** in  $L_d$  (Contradiction).
  - ◆ Suppose not. Then  $x$  is in  $H(M_j)$  by definition of  $L_d$ . But  $H(M_j) = H(M) = L_d$ , so  $x$  is in  $L_d$  (Contradiction).

- Since we derive a contradiction in either case, we conclude that our assumption  $H(M) = L_d$  was wrong, and in fact, there is no such TM  $M$ .

### Rules About Complements

Let  $L$  and  $\bar{L}$  be a language and its complement with respect to alphabet  $\{0, 1\}$ .

- If  $L$  is recursive, so is  $\bar{L}$ .
  - ◆ Proof: Find a TM  $M$  that accepts  $L$  by final state but always halts. Arrange for a TM  $M'$  to simulate  $M$ , but accept if and only if  $M$  halts before accepting.
- If  $L$  and  $\bar{L}$  are RE, then both are recursive.
  - ◆ Proof: Simulate TM's for both  $L$  and  $\bar{L}$  on separate tracks. One or the other is guaranteed to accept, so the simulating TM can always be made to halt.

### The Universal Language

$L_u$  = the set of binary strings consisting of a code for some TM  $M_i$  followed by some binary string  $w$ , such that  $w$  is in  $H(M_i)$ .

- Proof in reader that  $L_u$  is RE.
  - ◆ In essence: a TM can be treated as a stored-program device, just like a real computer.
  - ◆ Hard part of proof: Since  $M_i$  may have any number of states and tape symbols, one multitape TM  $M$  cannot simulate these states and symbols directly. Rather, it represents them as strings of 0's (as in the code we developed) and compares using scratch tapes.
- Proof  $L_u$  is not recursive: show  $\bar{L}_u$  is not RE.
  - ◆ Remember, if  $L_u$  were recursive, then  $\bar{L}_u$  would be recursive, and therefore RE.
- Proof that  $\bar{L}_u$  is not RE:
  - ◆ A *reduction* from  $L_d$  to  $\bar{L}_u$ : Show that if there is a TM for  $\bar{L}_u$ , then there is a TM for  $L_d$  (which we know there isn't).
  - ◆ Transform  $w$  by first checking that  $1w$  represents some TM  $M_i$  (i.e., it is of the form  $111codes111$ ). If so, produce  $1ww$  as input to a hypothetical  $\bar{L}_u$  TM. If not, reject  $w$ , since  $1w$  represents a TM that accepts everything.

- ◆ If  $1ww$  is produced, simulate the  $\overline{L_u}$  TM on this input. If it accepts, then TM  $M_i$  (represented by  $1w$ ) does not accept the  $i$ th string,  $w$ , so  $w$  is in  $L_d$ .
- ◆ If  $1ww$  is not in  $\overline{L_u}$ , then  $M_i$  does accept  $w$ , so  $w$  is not in  $L_d$ .
- Summary:
  - ◆  $L_d$  is undecidable (not recursive), and in fact not RE.
  - ◆  $L_u$  is undecidable, but RE.
  - ◆  $\overline{L_u}$  is like  $L_d$ , not RE.
  - ◆  $\overline{L_d}$  is like  $L_u$ , RE, although we did not prove this.

### Rice's Theorem

Essentially, any nontrivial property of *the language* of a TM is undecidable.

- Note the difference between a property of  $L(M)$  from a property about  $M$ :
  - ◆ Example:  $L(M) = \emptyset$  is a property of the language.
  - ◆ Example: “ $M$  has at least 100 states” is a property of the TM itself.
  - ◆ “ $= \emptyset$ ” is undecidable; “has 100 states” is easily decidable, just look at the code for  $M$  and count.

### Properties

A *property* of the RE languages is a set of strings, those that represent TM's in a certain class.

- Example: the property “is context-free” is the set of codes for all TM's  $M$  such that  $L(M)$  is a CFL.
- The property is “of languages” if TM's whose languages are the same either all have the property or none do.

### Proof of Rice's Theorem

Let  $P$  be any nontrivial property of the RE languages; i.e., at least one RE language has the property, and at least one does not.

- We shall prove that  $P$  (as a language, i.e., a set of TM codes) is undecidable.

- Assume  $\emptyset$  does not have property  $P$ .
  - ◆ If it does, consider  $\overline{P}$ .  $P$  is decidable if and only if  $\overline{P}$  is.
- Suppose  $P$  is decidable. Assume  $L$  is a language with property  $P$ , and  $\emptyset$  is a language without property  $P$ . We can decide  $L_u$  (something we know is impossible) as follows.
  - ◆ Given  $(M, w)$ , test if  $w$  is in  $H(M)$  as follows. First, we shall construct a TM  $N$  to accept either  $\emptyset$  or  $L$ , depending on whether  $M$  accepts  $w$ .
  - ◆  $N$  simulates  $M$  on  $w$ . Note that  $w$  is not input to  $N$ ; rather  $N$  writes  $w$  on a scratch tape and simulates  $M$  which is part of  $N$ 's own states.
  - ◆ If  $M$  accepts  $w$ ,  $N$  then simulates a TM  $M_L$  for language  $L$  on  $N$ 's own input  $x$ . If  $M_L$  accepts  $x$  then  $N$  accepts  $x$ .
  - ◆ If  $M$  never accepts  $w$ ,  $N$  never gets to simulate  $M_L$ , and therefore accepts  $\emptyset$ .
  - ◆ Feed the constructed  $N$  to the hypothetical  $P$  tester. Accept  $(M, w)$  if and only if  $N$  has property  $P$ .

### Consequences of Rice's Theorem

We cannot tell if a TM:

- Accepts  $\emptyset$ .
- Accepts a finite language.
- Accepts a regular language, a context free language, etc. etc.

### Reductions

To prove a problem  $P_1$  to be hard in some sense (e.g., undecidable), we can *reduce*  $P_2$ , a known hard problem, to  $P_1$ .

- For each instance  $w$  (string in)  $P_2$ , we construct an instance  $x$  of  $P_1$ , using some fixed algorithm.
  - ◆ The same algorithm must also turn a string  $w$  that is not in  $P_2$  into a string  $x$  that is not in  $P_1$ .
- We can then argue that if  $P_1$  were decidable, we could use the algorithm in which we transformed  $w$  to  $x$  and then tested  $x$  for membership in  $P_1$  as a way to decide  $P_2$ .
  - ◆ Since  $P_2$  is undecidable, we have a

contradiction of the assumption  $P_1$  is decidable.

- The same idea works for showing  $P_1$  not to be RE, but now  $P_2$  must be non-RE, and the transformation from instances of  $P_2$  to instances of  $P_1$  may be a procedure, not necessarily an algorithm.
- Common error: trying to do the reduction in the wrong direction.
